

On stationary Navier-Stokes flows around a rotating obstacle in two-dimensions

Mitsuo Higaki*

Yasunori Maekawa[†]Yuu Nakahara[‡]

Abstract We study the two-dimensional stationary Navier-Stokes equations describing the flows around a rotating obstacle. The unique existence of solutions and their asymptotic behavior at spatial infinity are established when the rotation speed of the obstacle and the given exterior force are sufficiently small.

Keywords Navier-Stokes equations · two-dimensional exterior flows · scale-criticality · flows around a rotating obstacle

1 Introduction

In this paper we consider the two-dimensional Navier-Stokes equations for viscous incompressible flows around a rotating obstacle in two-dimensions:

$$\begin{cases} \partial_t v - \Delta v + v \cdot \nabla v + \nabla q = g, & \operatorname{div} v = 0, & t > 0, y \in \Omega(t), \\ v = \alpha y^\perp, & & t > 0, y \in \partial\Omega(t). \end{cases} \quad (1)$$

Here $v = v(y, t) = (v_1(y, t), v_2(y, t))^\top$ and $q = q(y, t)$ are respectively unknown velocity field and pressure field, and $g(t, y) = (g_1(t, y), g_2(t, y))^\top$ is a given external force. The time dependent domain $\Omega(t)$ is defined as

$$\begin{aligned} \Omega(t) &= \{y \in \mathbb{R}^2 \mid y = O(\alpha t)x, x \in \Omega\}, \\ O(\alpha t) &= \begin{pmatrix} \cos \alpha t & -\sin \alpha t \\ \sin \alpha t & \cos \alpha t \end{pmatrix}, \end{aligned} \quad (2)$$

where Ω is an exterior domain in \mathbb{R}^2 with a smooth compact boundary, while the real number α represents the rotation speed of the obstacle $\Omega^c = \mathbb{R}^2 \setminus \Omega$. We use the standard notation for derivatives: $\partial_t = \frac{\partial}{\partial t}$, $\partial_j = \frac{\partial}{\partial x_j}$, $\Delta = \sum_{j=1}^2 \partial_j^2$, $\operatorname{div} v = \sum_{j=1}^2 \partial_j v_j$, $v \cdot \nabla v = \sum_{j=1}^2 v_j \partial_j v$. The vector x^\perp denotes the perpendicular: $x^\perp = (-x_2, x_1)^\top$. The system (1) describes the flow around the obstacle Ω^c which rotates with a constant angular velocity α , and the condition $v(t, y) = \alpha y^\perp$ on the boundary $\partial\Omega(t)$ represents the no-slip boundary condition. To remove the difficulty due to the time dependence of the fluid domain it is more convenient to analyze the system (1) in the reference frame:

$$y = O(\alpha t)x, \quad u(x, t) = O(\alpha t)^\top v(y, t), \quad p(x, t) = q(y, t), \quad f(x, t) = O(\alpha t)^\top g(y, t).$$

[‡]Mathematical Institute, Tohoku University, Japan. E-mail: yuu.nakahara.t3@dc.tohoku.ac.jp

Here M^\top denotes the transpose of a matrix M . Then (1) is equivalent with the equations in the time-independent domain Ω :

$$\begin{cases} \partial_t u - \Delta u - \alpha(x^\perp \cdot \nabla u - u^\perp) + \nabla p = -u \cdot \nabla u + f, & \operatorname{div} u = 0, \quad t > 0, \quad x \in \Omega, \\ u = \alpha x^\perp, & t > 0, \quad x \in \partial\Omega. \end{cases}$$

In this paper we are interested in the stationary solutions to this system. Thus we assume that f is independent of t and consider the elliptic system

$$\begin{cases} -\Delta u - \alpha(x^\perp \cdot \nabla u - u^\perp) + \nabla p = -u \cdot \nabla u + f, & \operatorname{div} u = 0, \quad x \in \Omega, \\ u = \alpha x^\perp, & x \in \partial\Omega. \end{cases} \quad (\text{NS}_\alpha)$$

To state our result let us introduce the function spaces used in this paper. As usual, the class $C_{0,\sigma}^\infty(\Omega)$ is defined as the set of smooth divergence free vector fields with compact support in Ω , and the homogeneous space $\dot{W}_{0,\sigma}^{1,2}(\Omega)$ is the closure of $C_{0,\sigma}^\infty(\Omega)$ with respect to the norm $\|\nabla f\|_{L^2(\Omega)}$. For a fixed number $s \geq 0$ we also introduce the weighted L^∞ space $L_s^\infty(\Omega)$ and its subspace $L_{s,0}^\infty(\Omega)$ as follows.

$$\begin{aligned} L_s^\infty(\Omega) &= \{f \in L^\infty(\Omega) \mid (1 + |x|)^s f \in L^\infty(\Omega)\}, \\ L_{s,0}^\infty(\Omega) &= \{f \in L_s^\infty(\Omega) \mid \lim_{R \rightarrow \infty} \operatorname{ess.\sup}_{|x| \geq R} |x|^s |f(x)| = 0\}. \end{aligned} \quad (3)$$

These spaces are equipped with the natural norm $\|f\|_{L_s^\infty(\Omega)} = \operatorname{ess.\sup}_{x \in \Omega} (1 + |x|)^s |f(x)|$. We denote by $L_{loc}^2(\overline{\Omega})$ the set of functions which belong to $L^2(\overline{\Omega} \cap K)$ for any compact set $K \subset \mathbb{R}^2$, and $W_{loc}^{k,2}(\overline{\Omega})$, $k = 1, 2, \dots$, is defined in the similar manner. Finally, for $r > 0$ the truncated domain Ω_r is defined as $\Omega_r = \{x \in \Omega \mid |x| < r\}$.

The main result of this paper is stated as follows.

Theorem 1.1 *There exists $\epsilon = \epsilon(\Omega) > 0$ such that the following statement holds. Assume that $f \in L^2(\Omega)^2$ is of the form $f = \operatorname{div} F$ with some $F \in L_2^\infty(\Omega)^{2 \times 2}$ and $F_{21} - F_{12} \in L^1(\Omega)$. If $\alpha \neq 0$ and*

$$|\alpha|^{\frac{1}{2}} |\log |\alpha|| + |\alpha|^{-\frac{1}{2}} |\log |\alpha|| (\|f\|_{L^2(\Omega)} + \|F\|_{L_2^\infty(\Omega)} + \|F_{21} - F_{12}\|_{L^1(\Omega)}) < \epsilon, \quad (4)$$

then there exists a solution $(u, \nabla p) \in (W_{loc}^{2,2}(\overline{\Omega}) \cap L_1^\infty(\Omega))^2 \times L_{loc}^2(\overline{\Omega})^2$ to (NS_α) , which is unique in a suitable class of functions (see Theorem 4.1 for the precise description). If $F \in L_{2,0}^\infty(\Omega)^{2 \times 2}$ in addition, then the solution u behaves as

$$u(x) = \beta \frac{x^\perp}{4\pi|x|^2} + o(|x|^{-1}), \quad |x| \rightarrow \infty, \quad (5)$$

where

$$\beta = \int_{\partial\Omega} y^\perp \cdot (T(u, p)\nu) \, d\sigma_y + \lim_{\delta \rightarrow 0} \int_{\Omega} e^{-\delta|y|^2} y^\perp \cdot f \, dy. \quad (6)$$

Here $T(u, p) = \nabla u + (\nabla u)^\top - p\mathbb{I}$, $\mathbb{I} = (\delta_{ij})_{1 \leq i, j \leq 2}$, denotes the Cauchy stress tensor, and ν is the outward unit normal vector to $\partial\Omega$.

Remark 1.2 (i) The smallness condition on f and F in (4) can be slightly improved with respect to the dependence on α ; see Theorem 4.1 for details.

(ii) Both conditions $F \in L_2^\infty(\Omega)^{2 \times 2}$ and $F_{21} - F_{12} \in L^1(\Omega)$ are critical in view of scaling. Note that the L^1 summability is needed only for the antisymmetric part of F . These conditions are not enough to ensure that u behaves like the circular flow $\beta \frac{x^\perp}{4\pi|x|^2}$ as $|x| \rightarrow \infty$, and the additional decay condition $F \in L_{2,0}^\infty(\Omega)^{2 \times 2}$ as in Theorem 1.1 is required to achieve this property.

(iii) The second term of the right-hand side of (6) is well-defined if $F \in L_{2,0}^\infty(\Omega)$ and $F_{21} - F_{12} \in L^1(\Omega)$. If F possesses an additional decay such as $L_{2+\gamma}^\infty(\Omega)$ with $\gamma \in (0, 1)$ then the order $o(|x|^{-1})$ in (5) is replaced by $O(|x|^{-1-\gamma})$ at least when $|\alpha|$ and given data f are further small depending on γ . The precise statement on this result is stated in Theorem 4.1.

As far as the authors know, Theorem 1.1 is the first general existence result of the flows around a rotating obstacle *in the two-dimensional case*. Before stating the idea of the proof of Theorem 1.1, let us recall some known results on the mathematical analysis of flows around a rotating obstacle.

So far the mathematical results on this topic have been obtained mainly for the three-dimensional problem, as listed below. For the nonstationary problem the existence of global weak solutions is proved by Borchers [1], and the unique existence of time-local regular solutions is shown by Hishida [17] and Geissert, Heck, and Hieber [15], while the global strong solutions for small data are obtained by Galdi and Silvestre [14]. The spectrum of the linear operator related to this problem is studied by Farwig and Neustupa [8]; see also the linear analysis by Hishida [18]. The existence of stationary solutions to the associated system is proved in [1], Silvestre [25], Galdi [11], and Farwig and Hishida [5]. In particular, in [11] the stationary flows with the decay order $O(|x|^{-1})$ are obtained, while the work of [5] is based on the weak L^3 framework, which is another natural scale-critical space for the three-dimensional Navier-Stokes equations. Our Theorem 1.1 is considered as a two-dimensional counterpart of the three-dimensional result of [11]. In 3D case the asymptotic profiles of these stationary flows at spatial infinity are studied by Farwig and Hishida [6, 7] and Farwig, Galdi, and Kyed [4], where it is proved that the asymptotic profiles are described by the Landau solutions, stationary self-similar solutions to the Navier-Stokes equations in $\mathbb{R}^3 \setminus \{0\}$. It is worthwhile to mention that, also in the two-dimensional case, the asymptotic profile is given by the stationary self-similar solution $c \frac{x^\perp}{|x|^2}$, as is shown in Theorem 1.1. The stability of the above stationary solutions has been well studied in the three-dimensional case; The global L^2 stability is proved in [14], and the local L^3 stability is obtained by Hishida and Shibata [20].

All results mentioned above are in the three-dimensional case, while only a few results are known so far for the flow around a rotating obstacle in the two-dimensional case. Recently an important progress has been made by Hishida [19], where the asymptotic behavior of the two-dimensional stationary Stokes flow around a rotating obstacle is investigated in details. The equations studied in [19] are written as

$$\begin{cases} -\Delta u - \alpha(x^\perp \cdot \nabla u - u^\perp) + \nabla p = f, & \operatorname{div} u = 0, & x \in \Omega, \\ u = b, & & x \in \partial\Omega. \end{cases} \quad (\text{S}_\alpha)$$

Here b is a given smooth function on $\partial\Omega$. It is proved in [19] that if the smooth external

force f satisfies the decay conditions

$$\int_{\Omega} |x| |f| dx < \infty, \quad f(x) = o(|x|^{-3}(\log |x|)^{-1}), \quad \text{as } |x| \rightarrow \infty, \quad (7)$$

then the solution u to (S_{α}) decaying at spatial infinity obeys the asymptotic expansion

$$u(x) = \frac{c_1 x^{\perp} - c_2 x}{4\pi |x|^2} + (1 + |\alpha|^{-1}) o(|x|^{-1}), \quad \text{as } |x| \rightarrow \infty, \quad (8)$$

where

$$\begin{aligned} c_1 &= \int_{\partial\Omega} y^{\perp} \cdot (T(u, p) + \alpha b \otimes y^{\perp}) \nu d\sigma_y + \int_{\Omega} y^{\perp} \cdot f dy, \\ c_2 &= \int_{\partial\Omega} b \cdot \nu d\sigma_y. \end{aligned} \quad (9)$$

The result of [19] leads to an important conclusion that the rotation of the obstacle resolves the Stokes paradox (see Chang and Finn [3] for the rigorous description of the Stokes paradox) as in the Oseen resolution. We recall that when the obstacle is translating with a constant velocity $u_{\infty} \in \mathbb{R}^2 \setminus \{0\}$ the Navier-Stokes flows have been constructed by Finn and Smith [9, 10] for small but nonzero u_{∞} through the analysis of the Oseen linearization; see also Galdi [13]. The resolution of the Stokes paradox for (S_{α}) is due to the fact that the rotation removes the logarithmic singularity of the associated fundamental solution, which has been well known for the Oseen problem.

As a reference to the 2D exterior problem related with ours, the reader is referred to a recent work by Hillairet and Wittwer [16], where the stationary problem of (1) is discussed when $\Omega(t) = \Omega = \{y \in \mathbb{R}^2 \mid |y| > 1\}$ and the boundary condition is given as $v = \alpha y^{\perp} + b$ with a smooth and time-independent b . We note that the stationary flow $\alpha \frac{y^{\perp}}{|y|^2}$ exactly solves this problem when $b = 0$. In [16] the stationary solutions are constructed around this explicit solution for sufficiently small b when the number α is large enough. Although the problem discussed in [16] is in fact different from ours due to the time-independent given data b in the original frame (1), the solutions obtained in [16] share a common property with the ones in Theorem 1.1 in view of their asymptotic behaviors at spatial infinity.

It is well known that the existence of stationary Navier-Stokes flows in two-dimensional exterior domains (hence, the obstacle is rest) is an open problem in general. Partial results related to this problem have been obtained by Galdi [12], Russo [24], Yamazaki [26], and Pileckas and Russo [23], where the solutions are constructed under some symmetry conditions on both domains and given data. In particular, the Navier-Stokes flows decaying in the scale-critical order $O(|x|^{-1})$ are obtained in [26] in this category. The uniqueness is also available again under some symmetry conditions, see Nakatsuka [22].

The stability of the stationary solutions obtained in [26, 16] or in Theorem 1.1 is a highly challenging issue due to their spatial decay in the scale-critical order in two-dimensions, and it is still an open question in general. The difficulty is brought from the fact that the Hardy inequality $\|\frac{1}{|x|}f\|_{L^2(\Omega)} \leq C\|\nabla f\|_{L^2(\Omega)}$, $f \in \dot{W}_0^{1,2}(\Omega)$, does not hold when Ω is an exterior domain in \mathbb{R}^2 . As far as the authors know, the only result available so far is [21] by the second author of this paper, where the local L^2 stability is established for the special solution $\alpha \frac{x^{\perp}}{|x|^2}$, $|\alpha| \ll 1$, when Ω is the exterior domain to the unit disk.

Finally, let us state the key idea for the proof of Theorem 1.1. Our approach is motivated by the linear analysis developed in [19], where (9) is obtained through the detailed analysis

of the fundamental solution associated to the system (S_α) in \mathbb{R}^2 . The expansion (8) strongly indicates that the similar asymptotics is valid also for the Navier-Stokes flow, since the leading profile in (8) is a stationary self-similar solution to the Navier-Stokes equations in $\mathbb{R}^2 \setminus \{0\}$. However, it is far from trivial to justify this idea directly from the results of [19]. Indeed, the condition (7) is slightly restrictive in handling the nonlinear term $u \cdot \nabla u$, and more seriously, the singularity on $|\alpha|$ in (8) for $0 < |\alpha| \ll 1$ can prevent us closing the nonlinear estimates. To overcome this difficulty we revisit the argument of [19] and improve the estimates of the remainder term for the linear problem by analyzing the fundamental solution to (S_α) in \mathbb{R}^2 ; see Theorem 3.1, Lemma 3.3, and Theorem 3.8. The nonlinear problem (NS_α) is solved by applying the Banach fixed point theorem, however, the argument becomes complicated since we have to control two kinds of norms; the one bounds the local quantity, while the other one controls the spatial decay. This machinery is needed since the flow in a far field region ($|x| \gg 1$) exhibits a different dependence on $|\alpha|$ from the flow in a finite fluid region. In order to close the nonlinear estimates it is important to distinguish these two dependences on $|\alpha|$ and to estimate their interaction through the nonlinearity carefully. We also note that the structure of the nonlinear term $\nabla \cdot (u \otimes u)$ is essential to solve (NS_α) in the scale-critical framework. Indeed, the symmetry of the tensor $u \otimes u$ leads to a crucial cancellation for the coefficient “ $\int_\Omega y^\perp \cdot (u \cdot \nabla u) dy$ ”, which removes a possible singularity caused by the scale-critical decay of the flow.

This paper is organized as follows. In Section 2 the basic results on the oscillatory integrals are collected, which are used to establish the pointwise estimates of the fundamental solution to (S_α) with a milder singularity on $|\alpha|$, $|\alpha| \ll 1$. In Section 3 the linearized problem (S_α) with $b = 0$ is studied in details. Section 3.1 is devoted to the analysis in \mathbb{R}^2 , while the exterior problem is discussed in Section 3.2. Finally the nonlinear problem (NS_α) is solved in Section 4.

2 Preliminaries

In this section we collect the results of the oscillatory integrals used in Section 3.1.

Lemma 2.1 *Let $\alpha \in \mathbb{R} \setminus \{0\}$ and let $m, r > 0$. Then we have*

$$\left| \int_0^\infty e^{i\alpha t} e^{-\frac{r^2}{t}} \frac{dt}{t^m} \right| + \left| \int_0^\infty e^{i\alpha t} \int_t^\infty e^{-\frac{r^2}{s}} \frac{ds}{s^{m+1}} dt \right| \leq C \min \left\{ \frac{1}{|\alpha| r^{2m}}, \frac{1}{|\alpha|^{\frac{1}{m+1}} r^{\frac{2m^2}{m+1}}} \right\}, \quad (10)$$

where $C = C(m)$ is independent of r and α . Moreover, for $m > 1$ we have

$$\int_0^\infty e^{-\frac{r^2}{t}} \frac{dt}{t^m} = \frac{\gamma(m-1)}{r^{2(m-1)}}, \quad \int_0^\infty \int_t^\infty e^{-\frac{r^2}{s}} \frac{ds}{s^{m+1}} dt = \frac{\gamma(m-1)}{r^{2(m-1)}}, \quad (11)$$

where $\gamma(\cdot)$ denotes the Euler gamma function.

Proof: The proof of (11) is a straightforward computation, and we omit the details. To show (10) let us take a positive constant $l = l(r, \alpha)$ which will be determined later and split the integral as

$$\int_0^\infty e^{i\alpha t} e^{-\frac{r^2}{t}} \frac{dt}{t^m} = \int_0^l e^{i\alpha t} e^{-\frac{r^2}{t}} \frac{dt}{t^m} + \int_l^\infty e^{i\alpha t} e^{-\frac{r^2}{t}} \frac{dt}{t^m}.$$

The first term is estimated without using the effect of oscillation:

$$\left| \int_0^l e^{i\alpha t} e^{-\frac{r^2}{t}} \frac{dt}{t^m} \right| = \frac{1}{r^{2m}} \left| \int_0^l e^{-\frac{r^2}{t}} \left(\frac{r^2}{t} \right)^m dt \right| \leq \frac{Cl}{r^{2m}}.$$

For the second term we use the effect of oscillation to obtain

$$\begin{aligned} \int_l^\infty e^{i\alpha t} e^{-\frac{r^2}{t}} \frac{dt}{t^m} &= \frac{1}{i\alpha} \int_l^\infty \frac{d}{dt} \left[e^{i\alpha t} \right] \frac{e^{-\frac{r^2}{t}}}{t^m} dt \\ &= \frac{1}{i\alpha} \left[e^{i\alpha t} \frac{e^{-\frac{r^2}{t}}}{t^m} \right]_{t=l}^{t=\infty} - \frac{1}{i\alpha} \int_l^\infty e^{i\alpha t} \left(\frac{r^2 e^{-\frac{r^2}{t}}}{t^{m+2}} - \frac{m e^{-\frac{r^2}{t}}}{t^{m+1}} \right) dt, \end{aligned}$$

which yields

$$\left| \int_l^\infty e^{i\alpha t} e^{-\frac{r^2}{t}} \frac{dt}{t^m} \right| \leq \frac{1}{|\alpha|} \left(\frac{e^{-\frac{r^2}{l}}}{l^m} + \frac{1}{r^{2(m+1)}} \int_l^\infty \left(\frac{r^2}{t} + m \right) \left(\frac{r^2}{t} \right)^{m+1} e^{-\frac{r^2}{t}} dt \right). \quad (12)$$

By taking the limit of $l = 0$ we observe that the left-hand side of (12) is then bounded from above by $\frac{C}{|\alpha| r^{2m}}$ in virtue of (11). On the other hand, the right-hand side of (12) is also bounded from above by $\frac{C}{|\alpha| l^m}$. Taking $l = r^{\frac{2m}{m+1}} |\alpha|^{-\frac{1}{m+1}}$, we have arrived at

$$\left| \int_0^\infty e^{i\alpha t} e^{-\frac{r^2}{t}} \frac{dt}{t^m} \right| \leq \frac{C}{|\alpha|^{\frac{1}{m+1}} r^{\frac{2m^2}{m+1}}}.$$

The estimate of the integral

$$\int_0^\infty e^{i\alpha t} \int_t^\infty e^{-\frac{r^2}{s}} \frac{ds}{s^{m+1}} dt$$

is obtained exactly in the same manner, and hence the details are omitted here. The proof is complete. \square

Lemma 2.2 *Let $m > 1$. Then we have*

$$\begin{aligned} &\int_0^\infty \left| e^{-\frac{|O(\alpha t)x-y|^2}{4t}} - e^{-\frac{|x|^2}{4t}} \right| \frac{dt}{t^m} + \int_0^\infty \int_t^\infty \left| e^{-\frac{|O(\alpha t)x-y|^2}{4s}} - e^{-\frac{|x|^2}{4s}} \right| \frac{ds}{s^{m+1}} dt \\ &\leq C \frac{|y|}{|x|^{2m-1}}, \quad |x| > 2|y|, \end{aligned} \quad (13)$$

and

$$\left| \int_0^\infty e^{i\alpha t} e^{-\frac{|x|^2}{4t}} \frac{dt}{t^m} \right| \leq C \min \left\{ \frac{1}{|\alpha||x|^{2m}}, \frac{1}{|x|^{2(m-1)}} \right\}, \quad |x| > 0. \quad (14)$$

Moreover, for $m > 1$ we have

$$\left| \int_0^\infty e^{i\alpha t} \int_t^\infty e^{-\frac{|x|^2}{4s}} \frac{ds}{s^{m+1}} dt \right| \leq C \min \left\{ \frac{1}{|\alpha||x|^{2m}}, \frac{1}{|x|^{2(m-1)}} \right\}, \quad |x| > 0. \quad (15)$$

Here $C = C(m)$ is independent of x , y , and α .

Proof: By using the Taylor formula with respect to y around $y = 0$, we see

$$e^{-\frac{|O(\alpha t)x - y|^2}{4t}} = e^{-\frac{|x|^2}{4t}} + \frac{\langle O(\alpha t)x, y \rangle}{2t} e^{-\frac{|x|^2}{4t}} + \frac{\langle y, Qy \rangle}{8t^2} e^{-\frac{|O(\alpha t)x - \theta y|^2}{4t}}, \quad (16)$$

where $Q = (O(\alpha t)x - \theta y) \otimes (O(\alpha t)x - \theta y) - 2t\mathbb{I}$ with $\theta = \theta(\alpha, t, x, y) \in (0, 1)$ and $\langle x, y \rangle = x \cdot y$. From

$$|O(\alpha t)x - \theta y| \geq |x| - |y| > \frac{|x|}{2} \quad \text{for } |x| > 2|y|,$$

Lemma 2.1 leads to

$$\begin{aligned} & \int_0^\infty \left| e^{-\frac{|O(\alpha t)x - y|^2}{4t}} - e^{-\frac{|x|^2}{4t}} \right| \frac{dt}{t^m} \\ & \leq C \left(|x||y| \int_0^\infty e^{-\frac{|x|^2}{4t}} \frac{dt}{t^{m+1}} + (|x|^2|y|^2 + |x||y|^3 + |y|^4) \int_0^\infty e^{-\frac{|x|^2}{16t}} \frac{dt}{t^{m+2}} \right) \\ & \leq \frac{C|y|}{|x|^{2m-1}}, \quad |x| > 2|y|. \end{aligned}$$

Similarly we have from Lemma 2.1,

$$\int_0^\infty \int_t^\infty \left| e^{-\frac{|O(\alpha t)x - y|^2}{4s}} - e^{-\frac{|x|^2}{4s}} \right| \frac{ds}{s^{m+1}} dt \leq \frac{C|y|}{|x|^{2m-1}}, \quad |x| > 2|y|.$$

The proof of (13) is complete. Since $m > 1$, Est.(14) and (15) are consequences of (10) and (11). The proof is complete. \square

3 Stokes system with a rotation effect

This section is devoted to the analysis of the linearized problem (S_α) , introduced in Section 1, with $b = 0$.

3.1 Linear estimate in the whole plane

In this section let us consider the linear problem in whole plane for $\alpha \in \mathbb{R} \setminus \{0\}$:

$$-\Delta u - \alpha(x^\perp \cdot \nabla u - u^\perp) + \nabla p = f, \quad \operatorname{div} u = 0, \quad x \in \mathbb{R}^2. \quad (S_{\alpha, \mathbb{R}^2})$$

The velocity $u \in W_{loc}^{1,2}(\mathbb{R}^2)^2$ is said to be a weak solution to $(S_{\alpha, \mathbb{R}^2})$ if (i) $\operatorname{div} u = 0$ in the sense of distributions, and (ii) u satisfies

$$\int_{\mathbb{R}^2} \nabla u \cdot \nabla \phi - \alpha(x^\perp \cdot \nabla u - u^\perp) \cdot \phi \, dx = \int_{\mathbb{R}^2} f \cdot \phi \, dx, \quad \text{for all } \phi \in C_{0,\sigma}^\infty(\mathbb{R}^2). \quad (17)$$

The fundamental solution to $(S_{\alpha, \mathbb{R}^2})$ plays a central role throughout this paper, which is defined as

$$\Gamma_\alpha(x, y) = \int_0^\infty O(\alpha t)^T K(O(\alpha t)x - y, t) \, dt,$$

where

$$K(x, t) = G(x, t)\mathbb{I} + H(x, t), \quad H(x, t) = \int_t^\infty \nabla^2 G(x, s) \, ds,$$

and $G(x, t)$ is the two-dimensional Gauss kernel

$$G(x, t) = \frac{1}{4\pi t} e^{-\frac{|x|^2}{4t}}.$$

The next theorem is the main result of this section, which extends the result of [19] to our functional setting. For $f \in L^2(\mathbb{R}^2)^2$ and $F \in L^2(\mathbb{R}^2)^{2 \times 2}$ we formally set

$$\begin{aligned} c[f] &= \lim_{\epsilon \rightarrow 0} \int_{\mathbb{R}^2} e^{-\epsilon|x|^2} x^\perp \cdot f \, dx, \\ \tilde{c}[F] &= \lim_{\epsilon \rightarrow 0} \int_{\mathbb{R}^2} e^{-\epsilon|x|^2} (F_{21} - F_{12}) \, dx. \end{aligned} \quad (18)$$

Note that if $f \in L^2(\mathbb{R}^2)^2$ is of the form $f = \operatorname{div} F$ with some $F \in L^1(\mathbb{R}^2)^{2 \times 2}$ then $c[f] = \tilde{c}[F]$. Moreover, if F is symmetric then $\tilde{c}[F] = 0$.

Theorem 3.1 *Let $\alpha \in \mathbb{R} \setminus \{0\}$. We formally set*

$$L[f](x) = \lim_{\epsilon \rightarrow 0} \int_{\mathbb{R}^2} e^{-\epsilon|y|^2} \Gamma_\alpha(x, y) f(y) \, dy. \quad (19)$$

Then the following statements hold.

(i) *Let $\gamma \leq 1$. Suppose that $f \in L^2(\mathbb{R}^2)^2$ satisfies $\operatorname{supp} f \subset B_R(0)$ for some $R > 0$. Then $u = L[f]$ is a weak solution to $(S_{\alpha, \mathbb{R}^2})$ and is written as*

$$u(x) = c[f] \frac{x^\perp}{4\pi|x|^2} + \mathcal{R}[f](x), \quad x \neq 0, \quad (20)$$

where $\mathcal{R}[f]$ satisfies for $\gamma \in [0, 1]$,

$$\sup_{|x| \geq 2R} |x|^{1+\gamma} |\mathcal{R}[f](x)| \leq C_1 \left(|\alpha|^{-\frac{1+\gamma}{2}} \|f\|_{L^1(\{|y| \leq R\})} + \| |y|^{1+\gamma} f \|_{L^1(\{|y| \leq R\})} \right), \quad (21)$$

while for $\gamma < 0$,

$$\begin{aligned} \sup_{|x| \geq 2R} |x|^{1+\gamma} |\mathcal{R}[f](x)| &\leq C_1 \left((|\alpha|^{-\frac{1+\gamma}{2}} + |\alpha|^{-\frac{1}{2}} R^\gamma) \|f\|_{L^1(\{|y| \leq R\})} \right. \\ &\quad \left. + \| |y|^{1+\gamma} f \|_{L^1(\{|y| \leq R\})} \right). \end{aligned} \quad (22)$$

Here C_1 is a numerical constant, and is independent of γ , α , R , and f .

(ii) *Let $\gamma \in (-1, 1]$. Suppose that $f \in L^2(\mathbb{R}^2)^2$ is of the form $f = \operatorname{div} F$ with some $F \in L_{2+\gamma}^\infty(\mathbb{R}^2)^{2 \times 2}$, and in addition that $\tilde{c}[F]$ in (18) converges when $\gamma \in (-1, 0]$. Then $u = L[f]$ is a weak solution to $(S_{\alpha, \mathbb{R}^2})$ and is written as*

$$u(x) = \tilde{c}[F] \frac{x^\perp}{4\pi|x|^2} + \mathcal{R}[f](x), \quad x \neq 0, \quad (23)$$

where $\mathcal{R}[f]$ satisfies for $R > 0$,

$$\begin{aligned} \sup_{|x| \geq 2R} |x|^{1+\gamma} |\mathcal{R}[f](x)| &\leq C_2 \left(\| |y|^{2+\gamma} F \|_{L^\infty(\{|y| \geq R\})} + \sup_{|x| \geq 2R} |x|^{-1+\gamma} \| y F \|_{L_y^1(\{|2|y| \leq |x|\})} \right. \\ &\quad + \sup_{|x| \geq 2R} \min \left\{ \frac{1}{|\alpha||x|^{2-\gamma}}, |x|^\gamma \right\} \| F \|_{L_y^1(\{|2|y| \leq |x|\})} \\ &\quad \left. + \sup_{|x| \geq 2R} |x|^\gamma \left| \lim_{\epsilon \rightarrow 0} \int_{2|y| \geq |x|} e^{-\epsilon|y|^2} (F_{21} - F_{12}) \, dy \right| \right). \end{aligned} \quad (24)$$

For each $\delta \in [0, 1)$ the constant C_2 is independent of $\gamma \in [-\delta, 1]$, α , R , and F .

Remark 3.2 Under the assumptions of (i) or (ii) in Theorem 3.1 it is not difficult to see that $L[f]$ belongs to $W_{loc}^{2,2}(\mathbb{R}^2)$. Set

$$p(x) = \int_{\mathbb{R}^2} \frac{x-y}{2\pi|x-y|^2} f(y) dy. \quad (25)$$

Then, ∇p belongs to $L^2(\mathbb{R}^2)^2$ under the assumptions of (i) or (ii) in Theorem 3.1 by the Calderón-Zygmund inequality, and as is shown in [19, Proposition 3.2], the pair $(L[f], \nabla p)$ satisfies $(S_{\alpha, \mathbb{R}^2})$ in the sense of distributions. In virtue of the uniqueness result stated in [19, Lemma 3.5], for any solution $(u, p) \in \dot{W}^{1,2}(\mathbb{R}^2)^2 \times \mathcal{S}'(\mathbb{R}^2)$ satisfying $(S_{\alpha, \mathbb{R}^2})$ in the sense of distributions, the velocity u is expressed as $u = u_\infty + L[f]$ for some constant vector $u_\infty \in \mathbb{R}^2$.

We note that in (ii) of Theorem 3.1 the coefficient $\tilde{c}[F]$ is always well-defined when $\gamma > 0$. The asymptotic expansion (20) for the case (i) is firstly established by [19, Proposition 3.2]. Indeed, for the case (i) it is shown in [19, Proposition 3.2] that $\mathcal{R}[f]$ decays at infinity as $O(|x|^{-2})$, while the singularity $|\alpha|^{-1}$ appears in the coefficient of the estimates there. The new ingredients in Theorem 3.1 are (21) and (24), where both the consistency in the weighted L^∞ spaces and the milder singularity on α for small $|\alpha|$ are essential to solve the nonlinear problem in Section 4. On the other hand, as in [19], the key step to prove Theorem 3.1 is the expansion and the pointwise estimate of the fundamental solution $\Gamma_\alpha(x, y)$, which are stated in Lemma 3.3 below. The fundamental solution $\Gamma_\alpha(x, y)$ is studied in details in [19, Proposition 3.1] and we will revisit the argument developed by [19] in the proof of this lemma.

Lemma 3.3 Set

$$L(x, y) = \frac{x^\perp \otimes y^\perp}{4\pi|x|^2}. \quad (26)$$

Then for $m = 0, 1$ the kernel $\Gamma_\alpha(x, y)$ satisfies

$$\begin{aligned} & |\nabla_y^m (\Gamma_\alpha(x, y) - L(x, y))| \\ & \leq C \left(\delta_{0m} \min \left\{ \frac{1}{|\alpha||x|^2}, \frac{1}{|\alpha|^{\frac{1}{2}}|x|} \right\} + |x|^{1-m} \min \left\{ \frac{1}{|\alpha||x|^3}, \frac{1}{|x|} \right\} + \frac{|y|^{2-m}}{|x|^2} \right), \quad (27) \\ & \text{for } |x| > 2|y|. \end{aligned}$$

Here δ_{0m} is the Kronecker delta and C is independent of x , y , and α .

Remark 3.4 The case $m = 0$ of (27) is obtained in [19, Proposition 3.1] but with $|\alpha|^{-1}$ dependence of the coefficients in the estimate. The case $m = 1$ is not stated explicitly in [19], although it can be handled in the similar spirit as in the case $m = 0$. In this sense Lemma 3.3 is not completely new, and is an improvement of [19, Proposition 3.1] with respect to the singularity on $|\alpha|$ for $|\alpha| \ll 1$.

Proof of Lemma 3.3: In principle, our proof of Lemma 3.3 will proceed along the line of [19, Proposition 3.1]. In fact, the only key difference of our proof for the case $m = 0$ is the

application of Lemmas 2.1, 2.2 in suitable parts. In the proof for the case $m = 1$ Ineq. (13) will be essentially used in addition.

Following the argument of [19, Section 3], we decompose $\Gamma_\alpha(x, y)$ as

$$\begin{aligned}
& \Gamma_\alpha(x, y) \\
&= \Gamma_\alpha^0(x, y) + \Gamma_\alpha^{11}(x, y) + \Gamma_\alpha^{12}(x, y) \\
&:= \int_0^\infty O(\alpha t)^T G(O(\alpha t)x - y, t) dt \\
&\quad + \int_0^\infty O(\alpha t)^T (O(\alpha t)x - y) \otimes (O(\alpha t)x - y) \int_t^\infty G(O(\alpha t)x - y, s) \frac{ds}{4s^2} dt \\
&\quad - \int_0^\infty O(\alpha t)^T \int_t^\infty G(O(\alpha t)x - y, s) \frac{ds}{2s} dt.
\end{aligned} \tag{28}$$

We also decompose $L(x, y)$ as follows.

$$\begin{aligned}
L(x, y) &= \frac{x \otimes y + x^\perp \otimes y^\perp}{4\pi|x|^2} + \frac{-3(x \otimes y) + x^\perp \otimes y^\perp}{8\pi|x|^2} + \frac{x \otimes y}{4\pi|x|^2} - \frac{x \otimes y + x^\perp \otimes y^\perp}{8\pi|x|^2} \\
&=: L^0(x, y) + L^{111}(x, y) + L^{112}(x, y) + L^{12}(x, y).
\end{aligned} \tag{29}$$

Then, by Lemma 2.1 the following representations hold:

$$\begin{aligned}
L^0(x, y) &= \int_0^\infty G(x, t) \frac{dt}{4t} \begin{pmatrix} x \cdot y & x^\perp \cdot y \\ -x^\perp \cdot y & x \cdot y \end{pmatrix}, \\
L^{111}(x, y) &= \int_0^\infty \int_t^\infty G(x, s) \frac{ds}{4s^2} dt \left(\frac{-3(x \otimes y) + (x^\perp \otimes y^\perp)}{2} \right), \\
L^{112}(x, y) &= \int_0^\infty \int_t^\infty G(x, s) \frac{ds}{16s^3} dt |x|^2 (x \otimes y), \\
L^{12}(x, y) &= - \int_0^\infty \int_t^\infty G(x, s) \frac{ds}{8s^2} dt \begin{pmatrix} x \cdot y & x^\perp \cdot y \\ -x^\perp \cdot y & x \cdot y \end{pmatrix},
\end{aligned} \tag{30}$$

where we have used the equality

$$x \otimes y + x^\perp \otimes y^\perp = \begin{pmatrix} x \cdot y & x^\perp \cdot y \\ -x^\perp \cdot y & x \cdot y \end{pmatrix}.$$

To prove (27) we observe that

$$\begin{aligned}
& |\nabla_y^m (\Gamma_\alpha(x, y) - L(x, y))| \\
&\leq |\nabla_y^m (\Gamma_\alpha^0(x, y) - L^0(x, y))| + |\nabla_y^m (\Gamma_\alpha^{11}(x, y) - L^{111}(x, y) - L^{112}(x, y))| \\
&\quad + |\nabla_y^m (\Gamma_\alpha^{12}(x, y) - L^{12}(x, y))|.
\end{aligned}$$

Let us estimate each term in the right-hand side of the above inequality. The key idea is to use the Taylor formula for $G(O(\alpha t)x - y, t')$ around $y = 0$ as follows.

$$G(O(\alpha t)x - y, t') = G(x, t') + \frac{\langle O(\alpha t)x, y \rangle}{2t'} G(x, t') + \frac{\langle y, Qy \rangle}{8t'^2} G(O(\alpha t)x - \theta y, t'), \tag{31}$$

where

$$Q = Q(x, \theta y, \alpha t, t') = (O(\alpha t)x - \theta y) \otimes (O(\alpha t)x - \theta y) - 2t'\mathbb{I},$$

and $\theta \in (0, 1)$. To estimate $\Gamma_\alpha^0(x, y) - L(x, y)$ we use the identity

$$\begin{aligned} O^T(\alpha t)\langle O(\alpha t)x, y \rangle &= \frac{1}{2} \begin{pmatrix} x \cdot y & x^\perp \cdot y \\ -x^\perp \cdot y & x \cdot y \end{pmatrix} \\ &\quad + \frac{\cos 2\alpha t}{2} \begin{pmatrix} x \cdot y & -x^\perp \cdot y \\ x^\perp \cdot y & x \cdot y \end{pmatrix} + \frac{\sin 2\alpha t}{2} \begin{pmatrix} x^\perp \cdot y & x \cdot y \\ -x \cdot y & x^\perp \cdot y \end{pmatrix}. \end{aligned} \quad (32)$$

Let $|x| > 2|y|$. Then we have from (31) and (32),

$$\begin{aligned} |\Gamma_\alpha^0(x, y) - L^0(x, y)| &= \left| \int_0^\infty O^T(\alpha t)G(x, t) dt \right. \\ &\quad + \int_0^\infty \frac{1}{2t} \left(O^T(\alpha t)\langle O(\alpha t)x, y \rangle - \frac{1}{2} \begin{pmatrix} x \cdot y & x^\perp \cdot y \\ -x^\perp \cdot y & x \cdot y \end{pmatrix} \right) G(x, t) dt \\ &\quad \left. + \int_0^\infty O^T(\alpha t) \frac{\langle y, Qy \rangle}{8t^2} G(O(\alpha t)x - \theta y, t) dt \right| \\ &\leq \left| \int_0^\infty O^T(\alpha t)G(x, t) dt \right| + C|x||y| \min \left\{ \frac{1}{|\alpha||x|^4}, \frac{1}{|x|^2} \right\} \\ &\quad + C|y|^2 \int_0^\infty ((|x|^2 + |x||y| + |y|^2)t^{-3} + t^{-2}) e^{-\frac{|x|^2}{16t}} dt. \end{aligned} \quad (33)$$

Here we have used (14) for the second term and used the condition $|x| > 2|y|$ for the third term to achieve the last line. Clearly the last term in the right-hand side of (33) is bounded from above by $C|y|^2|x|^{-2}$ for $|x| > 2|y|$, while in virtue of (10) the first term is estimated as

$$\left| \int_0^\infty O^T(\alpha t)G(x, t) dt \right| \leq C \min \left\{ \frac{1}{|\alpha||x|^2}, \frac{1}{|\alpha|^{\frac{1}{2}}|x|} \right\}, \quad |x| > 0. \quad (34)$$

Thus we have arrived at

$$\begin{aligned} |\Gamma_\alpha^0(x, y) - L^0(x, y)| &\leq C \left(\min \left\{ \frac{1}{|\alpha||x|^2}, \frac{1}{|\alpha|^{\frac{1}{2}}|x|} \right\} + |y| \min \left\{ \frac{1}{|\alpha||x|^3}, \frac{1}{|x|} \right\} + \frac{|y|^2}{|x|^2} \right), \quad |x| > 2|y|. \end{aligned} \quad (35)$$

Next we consider the derivative estimate for $\Gamma_\alpha^0(x, y) - L^0(x, y)$. Let us go back to the definition of $\Gamma_\alpha^0(x, y)$ in (28). Then $\partial_{y_k}(\Gamma_\alpha^0(x, y) - L^0(x, y))$ is computed as

$$\begin{aligned} &|\partial_{y_k}(\Gamma_\alpha^0(x, y) - L^0(x, y))| \\ &= \left| \int_0^\infty \left(\frac{O^T(\alpha t)(O(\alpha t)x - y)_k}{2t} G(O(\alpha t)x - y, t) - \frac{1}{4t} \partial_{y_k} \begin{pmatrix} x \cdot y & x^\perp \cdot y \\ -x^\perp \cdot y & x \cdot y \end{pmatrix} G(x, t) \right) dt \right| \\ &\leq \left| \int_0^\infty \frac{O^T(\alpha t)(O(\alpha t)x - y)_k}{2t} \left(G(O(\alpha t)x - y, t) - G(x, t) \right) dt \right| \\ &\quad + \left| \int_0^\infty \left(O^T(\alpha t)(O(\alpha t)x - y)_k - \frac{1}{2} \partial_{y_k} \begin{pmatrix} x \cdot y & x^\perp \cdot y \\ -x^\perp \cdot y & x \cdot y \end{pmatrix} \right) G(x, t) \frac{dt}{2t} \right|. \end{aligned} \quad (36)$$

By applying (13) the first term is bounded from above by $C \frac{(|x|+|y|)|y|}{|x|^3}$. To estimate the second term we observe that

$$\begin{aligned} & O^T(\alpha t)(O(\alpha t)x - y)_k - \frac{1}{2}\partial_{y_k} \begin{pmatrix} x \cdot y & x^\perp \cdot y \\ -x^\perp \cdot y & x \cdot y \end{pmatrix} \\ &= \begin{cases} \frac{\cos 2\alpha t}{2} \begin{pmatrix} x_1 & x_2 \\ -x_2 & x_1 \end{pmatrix} + \frac{\sin 2\alpha t}{2} \begin{pmatrix} -x_2 & x_1 \\ -x_1 & -x_2 \end{pmatrix} - y_1 O^T(\alpha t), & \text{if } k = 1, \\ \frac{\cos 2\alpha t}{2} \begin{pmatrix} x_2 & -x_1 \\ x_1 & x_2 \end{pmatrix} + \frac{\sin 2\alpha t}{2} \begin{pmatrix} x_1 & x_2 \\ -x_2 & x_1 \end{pmatrix} - y_2 O^T(\alpha t), & \text{if } k = 2, \end{cases} \quad (37) \end{aligned}$$

Then, by using (14) the second term in the right-hand side of (36) is bounded from above by $C(|x| + |y|) \min\{\frac{1}{|\alpha||x|^4}, \frac{1}{|x|^2}\}$. Hence we have shown that

$$|\partial_{y_k}(\Gamma_\alpha^0(x, y) - L^0(x, y))| \leq C \left(\frac{|y|}{|x|^2} + \min\left\{ \frac{1}{|\alpha||x|^3}, \frac{1}{|x|} \right\} \right), \quad |x| > 2|y|. \quad (38)$$

Exactly in the same way we obtain for $m = 0, 1$ and $|x| > 2|y|$,

$$\begin{aligned} & |\nabla_y^m(\Gamma_\alpha^{12}(x, y) - L^{12}(x, y))| \\ & \leq C \left(\delta_{0m} \min\left\{ \frac{1}{|\alpha||x|^2}, \frac{1}{|\alpha|^{\frac{1}{2}}|x|} \right\} + |y|^{1-m} \min\left\{ \frac{1}{|\alpha||x|^3}, \frac{1}{|x|} \right\} + \frac{|y|^{2-m}}{|x|^2} \right). \quad (39) \end{aligned}$$

Next we estimate the term $|\Gamma_\alpha^{11}(x, y) - L^{11}(x, y) - L^{112}(x, y)|$. By the Taylor expansion stated in (31) we find

$$\begin{aligned} \Gamma_\alpha^{11}(x, y) &= \Gamma_\alpha^{111}(x, y) + \Gamma_\alpha^{112}(x, y) + \Gamma_\alpha^{113}(x, y) \\ &:= \int_0^\infty O(\alpha t)^T(O(\alpha t)x - y) \otimes (O(\alpha t)x - y) \int_t^\infty G(x, s) \frac{ds}{4s^2} dt \\ &+ \int_0^\infty O(\alpha t)^T(O(\alpha t)x - y) \otimes (O(\alpha t)x - y) \int_t^\infty \langle O(\alpha t)x, y \rangle G(x, s) \frac{ds}{8s^3} dt \\ &+ \int_0^\infty O(\alpha t)^T(O(\alpha t)x - y) \otimes (O(\alpha t)x - y) \int_t^\infty \langle y, Qy \rangle G(O(\alpha t)x - \theta y, s) \frac{ds}{32s^4} dt. \end{aligned}$$

For the last term $\Gamma_\alpha^{113}(x, y)$ it is straightforward to see from (11) that, for $|x| > 2|y|$,

$$|\Gamma_\alpha^{113}(x, y)| \leq C|y|^2(|x| + |y|)^2 \int_0^\infty \int_t^\infty (|x|^2 + |y|^2 + s) e^{-\frac{|x|^2}{16s}} \frac{ds}{s^5} dt \leq C \frac{|y|^2}{|x|^2}. \quad (40)$$

To estimate the first two terms we observe

$$\begin{aligned} & O(\alpha t)^T(O(\alpha t)x - y) \otimes (O(\alpha t)x - y) \\ &= A_0 + (\cos \alpha t)A_1 + (\sin \alpha t)A_2 + \frac{\cos 2\alpha t}{2}A_3 + \frac{\sin 2\alpha t}{2}A_4, \end{aligned} \quad (41)$$

where

$$\begin{aligned} A_0(x, y) &= \frac{-3(x \otimes y) + (x^\perp \otimes y^\perp)}{2}, \quad A_1(x, y) = \begin{pmatrix} x_1^2 + y_1^2 & x_1x_2 + y_1y_2 \\ x_1x_2 + y_1y_2 & x_2^2 + y_2^2 \end{pmatrix}, \\ A_2(x, y) &= \begin{pmatrix} -x_1x_2 + y_1y_2 & x_1^2 + y_1^2 \\ -(x_2^2 + y_2^2) & x_1x_2 - y_1y_2 \end{pmatrix}, \quad A_3(x, y) = \begin{pmatrix} -x \cdot y & x^\perp \cdot y \\ -x^\perp \cdot y & -x \cdot y \end{pmatrix}, \\ A_4(x, y) &= \begin{pmatrix} -x^\perp \cdot y & -x \cdot y \\ x \cdot y & -x^\perp \cdot y \end{pmatrix}. \end{aligned}$$

Then, by using (41) and by applying (10) the term $\Gamma_\alpha^{111}(x, y)$ is estimated as

$$\begin{aligned}
& \left| \Gamma_\alpha^{111}(x, y) - L^{111}(x, y) \right| \\
&= \left| \int_0^\infty \int_t^\infty \left((\cos \alpha t) A_1 + (\sin \alpha t) A_2 + \frac{\cos 2\alpha t}{2} A_3 + \frac{\sin 2\alpha t}{2} A_4 \right) G(x, s) \frac{ds}{4s^2} dt \right| \\
&\leq |x| \min \left\{ \frac{1}{|\alpha||x|^3}, \frac{1}{|x|} \right\}, \quad |x| > 2|y|. \tag{42}
\end{aligned}$$

Next we see

$$\begin{aligned}
& \langle O(\alpha t)x, y \rangle O(\alpha t)^T (O(\alpha t)x - y) \otimes (O(\alpha t)x - y) \\
&= \frac{|x|^2}{2} x \otimes y + B_1(x, y) \cos 2\alpha t + B_2(x, y) \sin 2\alpha t + B_3(x, y, \alpha t), \tag{43}
\end{aligned}$$

where each component of the matrices B_1, B_2 is a fourth order polynomial of x, y written as a suitable sum of the terms $x_1^{l_1} x_2^{l_2} y_1^{k_1} y_2^{k_2}$ with $l_1 + l_2 = 3$ and $k_1 + k_2 = 1$, while B_3 is estimated as $|B_3| \leq C|x|^2|y|^2$ as long as $|x| > 2|y|$. Thus we have from (43) and (10),

$$\begin{aligned}
& \left| \Gamma_\alpha^{112}(x, y) - L^{112}(x, y) \right| \\
&\leq \left| \int_0^\infty \int_t^\infty \left(B_1(x, y) \cos 2\alpha t + B_2(x, y) \sin 2\alpha t \right) G(x, s) \frac{ds}{8s^3} dt \right| \\
&\quad + C|x|^2|y|^2 \int_0^\infty \int_t^\infty G(x, s) \frac{ds}{s^3} dt \\
&\leq C \left(|x| \min \left\{ \frac{1}{|\alpha||x|^3}, \frac{1}{|x|} \right\} + \frac{|y|^2}{|x|^2} \right), \quad |x| > 2|y|. \tag{44}
\end{aligned}$$

Summing up (40), (42), and (44), we obtain

$$\begin{aligned}
& |\Gamma_\alpha^{11}(x, y) - L^{111}(x, y) - L^{112}(x, y)| \\
&\leq C \left(\min \left\{ \frac{1}{|\alpha||x|^2}, \frac{1}{|\alpha|^{\frac{1}{2}}|x|} \right\} + |x| \min \left\{ \frac{1}{|\alpha||x|^3}, \frac{1}{|x|} \right\} + \frac{|y|^2}{|x|^2} \right), \quad |x| > 2|y|. \tag{45}
\end{aligned}$$

To estimate the derivatives in y of $\Gamma_\alpha^{11}(x, y)$ we recall the definition of $\Gamma_\alpha^{11}(x, y)$ in (28) and use (41), which leads to the representation

$$\begin{aligned}
\Gamma_\alpha^{11}(x, y) &= \int_0^\infty \int_t^\infty A_0 G(O(\alpha t)x - y, s) \frac{ds}{4s^2} dt \\
&+ \int_0^\infty \int_t^\infty \left((\cos \alpha t) A_1 + (\sin \alpha t) A_2 + \frac{\cos 2\alpha t}{2} A_3 + \frac{\sin 2\alpha t}{2} A_4 \right) G(O(\alpha t)x - y, s) \frac{ds}{4s^2} dt \\
&=: \tilde{\Gamma}_\alpha^{111}(x, y) + \tilde{\Gamma}_\alpha^{112}(x, y). \tag{46}
\end{aligned}$$

From the expression of $L^{111}(x, y)$ in (30), we have for $|x| > 2|y|$,

$$\begin{aligned}
& \left| \partial_{y_k} (\tilde{\Gamma}_\alpha^{111}(x, y) - L^{111}(x, y)) \right| \\
&= \left| \int_0^\infty \int_t^\infty (\partial_{y_k} A_0) \left(G(O(\alpha t)x - y, s) - G(x, s) \right) \frac{ds}{4s^2} dt \right. \\
&\quad + \int_0^\infty \int_t^\infty (O(\alpha t)x - y)_k A_0 \left(G(O(\alpha t)x - y, s) - G(x, s) \right) \frac{ds}{8s^3} dt \\
&\quad \left. + \int_0^\infty \int_t^\infty (O(\alpha t)x - y)_k A_0 G(x, s) \frac{ds}{8s^3} dt \right| \\
&\leq C \left(\frac{|x||y|}{|x|^3} + \frac{(|x|^2|y| + |x||y|^2)|y|}{|x|^5} + \frac{(|x|^2|y| + |x||y|^2)}{|x|^4} \right) \leq C \frac{|y|}{|x|^2}. \quad (47)
\end{aligned}$$

Next we estimate the derivatives of $\tilde{\Gamma}_\alpha^{112}(x, y)$, which are computed as

$$\begin{aligned}
& \partial_{y_k} \tilde{\Gamma}_\alpha^{112}(x, y) \\
&= \int_0^\infty \int_t^\infty \left((\cos \alpha t) \partial_{y_k} A_1 + (\sin \alpha t) \partial_{y_k} A_2 + \frac{\cos 2\alpha t}{2} \partial_{y_k} A_3 + \frac{\sin 2\alpha t}{2} \partial_{y_k} A_4 \right) \\
&\quad \times G(O(\alpha t)x - y, s) \frac{ds}{4s^2} dt \\
&\quad + \int_0^\infty \int_t^\infty (O(\alpha t)x - y)_k \left((\cos \alpha t) A_1 + (\sin \alpha t) A_2 + \frac{\cos 2\alpha t}{2} A_3 + \frac{\sin 2\alpha t}{2} A_4 \right) \\
&\quad \times G(O(\alpha t)x - y, s) \frac{ds}{8s^3} dt \\
&=: I_k(x, y) + II_k(x, y). \quad (48)
\end{aligned}$$

To estimate $I_k(x, y)$ we observe that

$$\begin{aligned}
& \left| \int_0^\infty \int_t^\infty \left((\cos \alpha t) \partial_{y_k} A_1 + (\sin \alpha t) \partial_{y_k} A_2 \right) G(O(\alpha t)x - y, s) \frac{ds}{4s^2} dt \right| \\
&\leq C|y| \int_0^\infty \int_t^\infty e^{-\frac{|x|^2}{16s}} \frac{ds}{s^3} dt \leq C \frac{|y|}{|x|^2}, \quad |x| > 2|y|, \quad (49)
\end{aligned}$$

and that

$$\begin{aligned}
& \left| \int_0^\infty \int_t^\infty \left(\frac{\cos 2\alpha t}{2} \partial_{y_k} A_3 + \frac{\sin 2\alpha t}{2} \partial_{y_k} A_4 \right) G(O(\alpha t)x - y, s) \frac{ds}{4s^2} dt \right| \\
&\leq \left| \int_0^\infty \int_t^\infty \left(\frac{\cos 2\alpha t}{2} \partial_{y_k} A_3 + \frac{\sin 2\alpha t}{2} \partial_{y_k} A_4 \right) \left(G(O(\alpha t)x - y, s) - G(x, s) \right) \frac{ds}{4s^2} dt \right| \\
&\quad + \left| \int_0^\infty \int_t^\infty \left(\frac{\cos 2\alpha t}{2} \partial_{y_k} A_3 + \frac{\sin 2\alpha t}{2} \partial_{y_k} A_4 \right) G(x, s) \frac{ds}{4s^2} dt \right| \\
&\leq C \frac{|y|}{|x|^2} + C \min \left\{ \frac{1}{|\alpha||x|^3}, \frac{1}{|x|} \right\}. \quad (50)
\end{aligned}$$

Here we have used (13) for the first term and (15) for the second term to derive the last line. It remains to estimate $II_k(x, y)$ in (48). Below we consider the case $k = 1$ only, for the case $k = 2$ is obtained in the same manner. The direct computation yields the following key

identity:

$$\begin{aligned} & (O(\alpha t)x - y)_1 (\cos(\alpha t)A_1 + \sin(\alpha t)A_2) \\ &= \frac{|x|^2}{2} \begin{pmatrix} x_1 & 0 \\ x_2 & 0 \end{pmatrix} + \cos(2\alpha t)D_1(x, y) + \sin(2\alpha t)D_2(x, y) + D_3(x, y, \alpha t). \end{aligned} \quad (51)$$

Here D_1 and D_2 are the matrices whose components are suitable sums of the third order polynomials of the form $x_1^{l_1}x_2^{l_2}y_1^{k_1}y_2^{k_2}$ with $l_1 + l_2 \geq 1$, while $D_3(x, y, \alpha t)$ is estimated as $|D_3| \leq C|x|^2|y|$ for $|x| > 2|y|$. Hence, recalling the expression of $L^{112}(x, y)$ in (30), we have

$$\begin{aligned} & \left| \int_0^\infty \int_t^\infty (O(\alpha t)x - y)_1 ((\cos \alpha t)A_1 + (\sin \alpha t)A_2) G(O(\alpha t)x - y, s) \frac{ds}{8s^3} dt - \partial_{y_1} L^{112}(x, y) \right| \\ &= \left| \int_0^\infty \int_t^\infty \left(\cos(2\alpha t)D_1 + \sin(2\alpha t)D_2 + D_3 \right) G(O(\alpha t)x - y, s) \frac{ds}{8s^3} dt \right| \\ &\leq \left| \int_0^\infty \int_t^\infty \left(\cos(2\alpha t)D_1 + \sin(2\alpha t)D_2 + D_3 \right) \left(G(O(\alpha t)x - y, s) - G(x, s) \right) \frac{ds}{8s^3} dt \right| \\ &\quad + \left| \int_0^\infty \int_t^\infty \left(\cos(2\alpha t)D_1 + \sin(2\alpha t)D_2 + D_3 \right) G(x, s) \frac{ds}{8s^3} dt \right| \\ &\leq C \frac{|y|}{|x|^2} + C \min \left\{ \frac{1}{|\alpha||x|^3}, \frac{1}{|x|} \right\}. \end{aligned} \quad (52)$$

Here, we have again applied (13) for the first term and (15) for the second term to derive the last line. Finally we have

$$\begin{aligned} & \left| \int_0^\infty \int_t^\infty (O(\alpha t)x - y)_1 \left(\frac{\cos 2\alpha t}{2} A_3 + \frac{\sin 2\alpha t}{2} A_4 \right) G(O(\alpha t)x - y, s) \frac{ds}{8s^3} dt \right| \\ &\leq C(|x| + |y|)|x||y| \int_0^\infty \int_t^\infty e^{-\frac{|x|^2}{16s}} \frac{ds}{s^4} dt \leq C \frac{|y|}{|x|^2}, \quad |x| > 2|y|. \end{aligned} \quad (53)$$

Collecting (49), (50), (52), and (53), we have shown that

$$\left| \partial_{y_1} (\tilde{\Gamma}_\alpha^{112}(x, y) - L^{112}(x, y)) \right| \leq C \left(\frac{|y|}{|x|^2} + \min \left\{ \frac{1}{|\alpha||x|^3}, \frac{1}{|x|} \right\} \right). \quad (54)$$

The estimate of $\partial_{y_2} (\tilde{\Gamma}_\alpha^{112}(x, y) - L^{112}(x, y))$ is obtained in the similar manner. Thus, from (47) and (54) we have obtained the estimates of the derivatives in y for $\Gamma_\alpha^{11}(x, y)$. The proof of Lemma 3.3 is complete. \square

Proof of Theorem 3.1: The assertion that $u = L[f]$ is a weak solution to $(S_{\alpha, \mathbb{R}^2})$ (whose definitions are stated in the beginning in this section) follows from a similar argument as in [19, Proposition 3.2]. So we omit the details on this part and we focus on the proof for the estimates of u here. (i) Let $\gamma \leq 1$. Suppose that $\text{supp } f \subset B_R(0)$. Note that $(4\pi|x|^2)^{-1}(y^\perp \cdot f(y))x^\perp = L(x, y)f(y)$ holds. Let $|x| \geq 2R$. Then we have from Lemma

3.3 with $m = 0$,

$$\begin{aligned}
& \left| \int_{\mathbb{R}^2} \Gamma_\alpha(x, y) f \, dy - c[f] \frac{x^\perp}{4\pi|x|^2} \right| \\
&= \left| \int_{|y| \leq R} (\Gamma_\alpha(x, y) - L(x, y)) f \, dy \right| \\
&\leq C \int_{|y| \leq R} \left(\min \left\{ \frac{1}{|\alpha||x|^2}, \frac{1}{|\alpha|^{\frac{1}{2}}|x|} \right\} + |x| \min \left\{ \frac{1}{|\alpha||x|^3}, \frac{1}{|x|} \right\} + \frac{|y|^2}{|x|^2} \right) |f| \, dy,
\end{aligned}$$

which implies $L[f](x) = c[f] \frac{x^\perp}{4\pi|x|^2} + \mathcal{R}[f](x)$ with

$$\begin{aligned}
|x|^{1+\gamma} |\mathcal{R}[f](x)| &\leq C \left(\min \left\{ \frac{1}{|\alpha||x|^{1-\gamma}}, \frac{|x|^\gamma}{|\alpha|^{\frac{1}{2}}} \right\} \|f\|_{L^1(\{|y| \leq R\})} \right. \\
&\quad \left. + \min \left\{ \frac{1}{|\alpha||x|^{1-\gamma}}, |x|^{1+\gamma} \right\} \|f\|_{L^1(\{|y| \leq R\})} + \| |y|^{1+\gamma} f \|_{L^1(\{|y| \leq R\})} \right). \tag{55}
\end{aligned}$$

Here C is independent of x, R, α, γ , and f . Then we use the inequality for $\gamma \in [0, 1]$,

$$\min \left\{ \frac{1}{|\alpha||x|^{1-\gamma}}, \frac{|x|^\gamma}{|\alpha|^{\frac{1}{2}}} \right\} \leq |\alpha|^{-\frac{1+\gamma}{2}}, \quad \min \left\{ \frac{1}{|\alpha||x|^{1-\gamma}}, |x|^{1+\gamma} \right\} \leq |\alpha|^{-\frac{1+\gamma}{2}}, \tag{56}$$

which leads to (21). On the other hand, when $\gamma < 0$ and $|x| \geq 2R$ we have

$$\begin{aligned}
\min \left\{ \frac{1}{|\alpha||x|^{1-\gamma}}, \frac{|x|^\gamma}{|\alpha|^{\frac{1}{2}}} \right\} &\leq |\alpha|^{-\frac{1+\gamma}{2}} + |\alpha|^{-\frac{1}{2}} (2R)^\gamma, \\
\min \left\{ \frac{1}{|\alpha||x|^{1-\gamma}}, |x|^{1+\gamma} \right\} &\leq |\alpha|^{-\frac{1+\gamma}{2}} + |\alpha|^{-\frac{1}{2}} (2R)^\gamma, \tag{57}
\end{aligned}$$

which leads to (22).

(ii) Let $\gamma \in (-1, 1]$. From the integration by parts we see

$$\begin{aligned}
\int_{\mathbb{R}^2} e^{-\epsilon|y|^2} \Gamma_\alpha(x, y) f \, dy &= - \int_{\mathbb{R}^2} e^{-\epsilon|y|^2} \nabla_y \Gamma_\alpha(x, y) F \, dy + 2\epsilon \int_{\mathbb{R}^2} e^{-\epsilon|y|^2} \Gamma_\alpha(x, y) y^T F \, dy \\
&= - \int_{\mathbb{R}^2} e^{-\epsilon|y|^2} \nabla_y (\Gamma_\alpha(x, y) - L(x, y)) F \, dy - \int_{\mathbb{R}^2} e^{-\epsilon|y|^2} \nabla_y L(x, y) F \, dy \\
&\quad + 2\epsilon \int_{\mathbb{R}^2} e^{-\epsilon|y|^2} \Gamma_\alpha(x, y) y^T F \, dy.
\end{aligned}$$

Note that $-\nabla_y L(x, y) F = (F_{21} - F_{12}) \frac{x^\perp}{4\pi|x|^2}$ by the definition of $L(x, y)$. Moreover, we have $|\Gamma_\alpha(x, y)| \leq C(\alpha, |x|)|y|^{-1}$ for $|y| > 2|x|$ by [19, Proposition 3.1], and $\int_{|y| \leq 2|x|} |\Gamma_\alpha(x, y)| \, dy \leq C'(\alpha, |x|) < \infty$ by [19, Lemma 3.3], which implies

$$\lim_{\epsilon \rightarrow 0} \epsilon \int_{\mathbb{R}^2} e^{-\epsilon|y|^2} \Gamma_\alpha(x, y) y^T F \, dy = 0$$

for $F \in L_{2+\gamma}^\infty(\mathbb{R}^2)^{2 \times 2}$, $\gamma > -2$. Hence we have

$$\begin{aligned}
u(x) = L[f](x) &= - \int_{|y| < \frac{|x|}{2}} \nabla_y (\Gamma_\alpha(x, y) - L(x, y)) F \, dy - \int_{|y| \geq \frac{|x|}{2}} \nabla_y \Gamma_\alpha(x, y) F \, dy \\
&\quad - \lim_{\epsilon \rightarrow 0} \int_{|y| \geq \frac{|x|}{2}} e^{-\epsilon|y|^2} (F_{21} - F_{12}) \, dy \frac{x^\perp}{4\pi|x|^2} + \tilde{c}[F] \frac{x^\perp}{4\pi|x|^2}. \tag{58}
\end{aligned}$$

The sum of the first three terms of the right-hand side of this equality is denoted by $\mathcal{R}[f]$. To estimate $\mathcal{R}[f]$ we firstly observe from Lemma 3.3,

$$\begin{aligned} & \left| \int_{|y| < \frac{|x|}{2}} \nabla_y (\Gamma_\alpha(x, y) - L(x, y)) F \, dy \right| \\ & \leq C \left(\frac{1}{|x|^2} \int_{|y| < \frac{|x|}{2}} |y F| \, dy + \min \left\{ \frac{1}{|\alpha||x|^3}, \frac{1}{|x|} \right\} \int_{|y| < \frac{|x|}{2}} |F| \, dy \right), \quad x \neq 0. \end{aligned} \quad (59)$$

Next we have from the direct calculation

$$|(\nabla_x K)(x, t)| \leq C \left(t^{-\frac{3}{2}} e^{-\frac{|x|^2}{16t}} + \int_t^\infty s^{-\frac{5}{2}} e^{-\frac{|x|^2}{16s}} \, ds \right),$$

which implies

$$\int_0^\infty |(\nabla K)(O(\alpha t)x, t)| \, dt \leq \frac{C}{|x|}, \quad x \neq 0.$$

Then by the transformation of the variables $y = O(\alpha t)z$ we have

$$\begin{aligned} & \left| \int_{|y| \geq \frac{|x|}{2}} \nabla_y \Gamma_\alpha(x, y) F \, dy \right| \\ & \leq \int_{|y| \geq \frac{|x|}{2}} \left(\int_0^\infty |(\nabla K)(O(\alpha t)x - y, t)| \, dt \right) |F(y)| \, dy \\ & \leq \| |y|^{2+\gamma} F \|_{L^\infty(\{2|y| \geq |x|\})} \int_{|z| \geq \frac{|x|}{2}} \left(\int_0^\infty |(\nabla K)(O(\alpha t)(x - z), t)| \, dt \right) |z|^{-2-\gamma} \, dz \\ & \leq C \| |y|^{2+\gamma} F \|_{L^\infty(\{2|y| \geq |x|\})} \int_{|z| \geq \frac{|x|}{2}} |x - z|^{-1} |z|^{-2-\gamma} \, dz \\ & \leq \frac{C}{|x|^{1+\gamma}} \| |y|^{2+\gamma} F \|_{L^\infty(\{2|y| \geq |x|\})}. \end{aligned} \quad (60)$$

Here C is independent of x and is also uniform in $\gamma \in [-\delta, 1]$ for each fixed $\delta \in [0, 1]$. Collecting (58), (59), and (60), we obtain (23) and (24). The proof of Theorem 3.1 is complete. \square

As in [19], next we consider the regularized system in \mathbb{R}^2 :

$$\epsilon u_\epsilon - \Delta u_\epsilon - \alpha(x^\perp \cdot \nabla u_\epsilon - u_\epsilon^\perp) + \nabla p_\epsilon = f, \quad \operatorname{div} u_\epsilon = 0, \quad x \in \mathbb{R}^2, \quad (\mathbf{S}_{\alpha, \mathbb{R}^2}^\epsilon)$$

where ϵ is a small positive constant. Let us introduce the integral kernel $\Gamma_\alpha^\epsilon(x, y)$ as

$$\Gamma_\alpha^\epsilon(x, y) = \int_0^\infty e^{-\epsilon t} O(\alpha t)^T K(O(\alpha t)x - y, t) \, dt, \quad x \neq y. \quad (61)$$

In virtue of the positive ϵ , the integral in (61) converges absolutely for $x \neq y$. Furthermore, the velocity u_ϵ defined by

$$u_\epsilon(x) = \int_{\mathbb{R}^2} \Gamma_\alpha^\epsilon(x, y) f(y) \, dy, \quad f \in L^2(\Omega)^2, \quad (62)$$

satisfies $(\mathbf{S}_{\alpha, \mathbb{R}^2}^\epsilon)$ in the sense of distributions with a suitable pressure ∇p_ϵ . The next lemma will be used in the proof of Theorem 3.8.

Lemma 3.5 Let $\alpha \in \mathbb{R} \setminus \{0\}$ and $\gamma \in (-1, 1]$. Suppose that $f \in L^2(\Omega)^2$ is of the form $f = \operatorname{div} F$ with some $F \in L_{2+\gamma}^\infty(\mathbb{R}^2)^{2 \times 2}$. Then there is $\theta > 0$ such that u_ϵ defined by (62) satisfies for $R > 1$,

$$\sup_{|x| \geq 2R} |x|^\theta |u_\epsilon(x)| \leq C(\|F\|_{L_{2+\gamma}^\infty(\{|y| \geq R\})} + \|F\|_{L_y^1(\{|y| \leq R\})}). \quad (63)$$

Here the constant C is independent of ϵ .

Proof: In the same way as in the proof of Lemma 3.3, we define $L^\epsilon = L^\epsilon(x, y)$ by

$$L^\epsilon(x, y) := L^{\epsilon,0}(x, y) + L^{\epsilon,111}(x, y) + L^{\epsilon,112}(x, y) + L^{\epsilon,12}(x, y),$$

where

$$\begin{aligned} L^{\epsilon,0}(x, y) &= \int_0^\infty e^{-\epsilon t} G(x, t) \frac{dt}{4t} \begin{pmatrix} x \cdot y & x^\perp \cdot y \\ -x^\perp \cdot y & x \cdot y \end{pmatrix}, \\ L^{\epsilon,111}(x, y) &= \int_0^\infty \int_t^\infty e^{-\epsilon t} G(x, s) \frac{ds}{4s^2} dt \left(\frac{-3(x \otimes y) + (x^\perp \otimes y^\perp)}{2} \right), \\ L^{\epsilon,112}(x, y) &= \int_0^\infty \int_t^\infty e^{-\epsilon t} G(x, s) \frac{ds}{16s^3} dt |x|^2 (x \otimes y), \\ L^{\epsilon,12}(x, y) &= - \int_0^\infty \int_t^\infty e^{-\epsilon t} G(x, s) \frac{ds}{8s^2} dt \begin{pmatrix} x \cdot y & x^\perp \cdot y \\ -x^\perp \cdot y & x \cdot y \end{pmatrix}, \end{aligned}$$

Then we have

$$\begin{aligned} |\nabla_y L^\epsilon(x, y)| &\leq C|x| \left(\int_0^\infty e^{-\frac{|x|^2}{4t}} \frac{dt}{t^2} + \int_0^\infty \int_t^\infty e^{-\frac{|x|^2}{4s}} \frac{ds}{s^3} dt + |x|^2 \int_0^\infty \int_t^\infty e^{-\frac{|x|^2}{4s}} \frac{ds}{s^4} dt \right) \\ &\leq \frac{C}{|x|}, \quad |x| > 0, \end{aligned} \quad (64)$$

where the constant C is independent of α and ϵ . By the integration by parts we rewrite u_ϵ as

$$\begin{aligned} u_\epsilon(x) &= - \int_{|y| < \frac{|x|}{2}} \nabla_y (\Gamma_\alpha^\epsilon(x, y) - L^\epsilon(x, y)) F dy - \int_{|y| \geq \frac{|x|}{2}} \nabla_y \Gamma_\alpha^\epsilon(x, y) F dy \\ &\quad - \int_{|y| < \frac{|x|}{2}} \nabla_y L^\epsilon(x, y) F dy. \end{aligned} \quad (65)$$

Then, proceeding as in the proof of Lemma 3.3, we obtain

$$|\nabla_y (\Gamma_\alpha^\epsilon(x, y) - L^\epsilon(x, y))| \leq C \left(\frac{|y|}{|x|^2} + \min \left\{ \frac{1}{|\alpha||x|^3}, \frac{1}{|x|} \right\} \right), \quad |x| > 2|y|, \quad (66)$$

where C is independent of x, y, α , and ϵ . Then we have

$$\begin{aligned} &\left| \int_{|y| < \frac{|x|}{2}} \nabla_y (\Gamma_\alpha^\epsilon(x, y) - L^\epsilon(x, y)) F dy \right| \\ &\leq \frac{C}{|x|} \|F\|_{L_y^1(\{|2|y| \leq |x|\})} \\ &\leq \frac{C}{|x|^\theta} (\|F\|_{L_{2+\gamma}^\infty(\{|y| \geq R\})} + \|F\|_{L_y^1(\{|y| \leq R\})}), \quad |x| > 1, \end{aligned} \quad (67)$$

for $0 < \theta < \min\{1 + \gamma, 1\}$. The second term in the right-hand side of (65) is also estimated as in the proof of Lemma 3.3, resulting the estimate

$$\left| \int_{|y| \geq \frac{|x|}{2}} \nabla_y \Gamma_\alpha^\epsilon(x, y) F \, dy \right| \leq \frac{C}{|x|^{1+\gamma}} \|F\|_{L_{2+\gamma}^\infty(\{|2|y| \geq |x|\})}. \quad (68)$$

For the last term in the right-hand side of (65) it is straightforward from (64) to see for $|x| > 1$,

$$\left| \int_{|y| < \frac{|x|}{2}} \nabla_y L^\epsilon(x, y) F \, dy \right| \leq \frac{C}{|x|^\theta} (\|F\|_{L_{2+\gamma}^\infty(\{|y| \geq R\})} + \|F\|_{L_y^1(\{|y| \leq R\})}). \quad (69)$$

Collecting (67), (68), and (69), we obtain (63). This completes the proof. \square

3.2 Linear estimate in the exterior domain

In this subsection we study the asymptotic estimates for solutions to the Stokes system in the exterior domain

$$\begin{cases} -\Delta u - \alpha(x^\perp \cdot \nabla u - u^\perp) + \nabla p = f, & \operatorname{div} u = 0, & x \in \Omega, \\ u = 0, & x \in \partial\Omega. \end{cases} \quad (\mathbf{S}_\alpha)$$

Here $\alpha \in \mathbb{R} \setminus \{0\}$ is a given constant. We fix $R_0 \geq 1$ large enough so that $\mathbb{R}^2 \setminus \Omega \subset B_{R_0}(0)$ holds. As in the previous section, for $f \in L^2(\Omega)^2$ and $F \in L^2(\Omega)^{2 \times 2}$ we formally set

$$\begin{aligned} c_\Omega[f] &= \lim_{\epsilon \rightarrow 0} \int_\Omega e^{-\epsilon|x|^2} x^\perp \cdot f \, dx, \\ \tilde{c}_\Omega[F] &= \lim_{\epsilon \rightarrow 0} \int_\Omega e^{-\epsilon|x|^2} (F_{21} - F_{12}) \, dx. \end{aligned} \quad (70)$$

Note that these are well-defined at least when $f = \operatorname{div} F$ with $F \in L_{2+\gamma}^\infty(\Omega)^{2 \times 2}$ for some $\gamma > 0$, and $c_\Omega[f] = \tilde{c}_\Omega[F]$ holds in this case if the generalized traces $n \cdot (x_2 \vec{F}_1)$, $n \cdot (x_1 \vec{F}_2)$ on $\partial\Omega$ are zero in addition. Here we have set $F = (\vec{F}_1, \vec{F}_2)$. In general, we have the following.

Lemma 3.6 *Let $f \in L^2(\Omega)^2$ be of the form $f = \operatorname{div} F$ for some $F \in L_{2,0}^\infty(\Omega)^{2 \times 2}$ and $F_{21} - F_{12} \in L^1(\Omega)$. Then both $c_\Omega[f]$ and $\tilde{c}_\Omega[F]$ converge.*

Proof: It is trivial that $\tilde{c}_\Omega[F]$ converges. Let $\varphi \in C_0^\infty(\mathbb{R}^2)$ be a cut-off function such that $\varphi(x) = 1$ for $|x| \leq R_0$ and $\varphi(x) = 0$ for $|x| \geq 2R_0$. The convergence of $c_\Omega[f]$ easily follows from the integration by parts:

$$\begin{aligned} c_\Omega[f] &= \int_\Omega x^\perp \cdot f \varphi \, dx - \lim_{\epsilon \rightarrow 0} \int_\Omega F \nabla (e^{-\epsilon|x|^2} x^\perp (1 - \varphi)) \, dx \\ &= \int_\Omega x^\perp \cdot f \varphi \, dx + \tilde{c}_\Omega[F] + \int_\Omega (F_{12} - F_{21}) \varphi \, dx \\ &\quad + \int_\Omega \nabla \varphi \cdot (F x^\perp) \, dx + \lim_{\epsilon \rightarrow 0} \int_\Omega e^{-\epsilon|x|^2} 2\epsilon x \cdot (F x^\perp) (1 - \varphi) \, dx. \end{aligned} \quad (71)$$

The last term in the right-hand side of (71) vanishes in virtue of the decay $|F(x)| = o(|x|^{-2})$ as $|x| \rightarrow \infty$. In particular, we have

$$c_\Omega[f] = \tilde{c}_\Omega[F] + \int_\Omega (x^\perp \cdot f + F_{12} - F_{21})\varphi + \nabla\varphi \cdot (Fx^\perp) dx. \quad (72)$$

The proof is complete. \square

Let us denote by $T(u, p)$ the stress tensor, which is defined as

$$T(u, p) = Du - p\mathbb{I}, \quad Du = \nabla u + (\nabla u)^\top, \quad \mathbb{I} = (\delta_{jk})_{1 \leq j, k \leq 2}. \quad (73)$$

The next lemma is a counterpart of [19, Theorem 2.1] in our functional setting. We recall that the truncated domain Ω_r is defined in Section 1 before the statement of Theorem 1.1.

Lemma 3.7 *Let $\alpha \in \mathbb{R} \setminus \{0\}$ and $\gamma \in (-1, 1]$. Suppose that $(u, \nabla p) \in W_{loc}^{2,2}(\overline{\Omega})^2 \times L_{loc}^2(\overline{\Omega})^2$, $\|\nabla u\|_{L^2(\Omega)} < \infty$, is a solution to the system (S_α) , and that $f \in L^2(\Omega)^2$ is given by $f = \operatorname{div} F$ with some $F \in L_{2+\gamma}^\infty(\Omega)^{2 \times 2}$. Assume in addition that $\tilde{c}_\Omega[F]$ converges when $\gamma \in (-1, 0]$. Then u is represented as*

$$u(x) = u_\infty + \beta \frac{x^\perp}{4\pi|x|^2} + \mathcal{R}(x), \quad x \in \Omega \setminus \{0\}, \quad (74)$$

with some constant vector $u_\infty \in \mathbb{R}^2$ and $\beta \in \mathbb{R}$, and \mathcal{R} satisfies

$$\begin{aligned} \sup_{|x| \geq 4R_0} |x|^{1+\gamma} |\mathcal{R}(x)| &\leq C \left(\sup_{|x| \geq 2R_0} |x|^{2+\gamma} |F(x)| + \sup_{|x| \geq 4R_0} |x|^{-1+\gamma} \|yF\|_{L_y^1(\Omega_{|x|/2})} \right. \\ &\quad + \sup_{|x| \geq 4R_0} \min \left\{ \frac{1}{|\alpha||x|^{2-\gamma}}, |x|^\gamma \right\} \|F\|_{L_y^1(\Omega_{|x|/2})} \\ &\quad \left. + \sup_{|x| \geq 4R_0} |x|^\gamma \left| \lim_{\epsilon \rightarrow 0} \int_{2|y| \geq |x|} e^{-\epsilon|y|^2} (F_{21} - F_{12}) dy \right| \right) \\ &\quad + C(|\alpha|^{-\frac{1+\gamma}{2}} + |\alpha|^{-\frac{1}{2}} + 1) (\|F\|_{L^2(\Omega_{2R_0})} + (1 + |\alpha|) \|\nabla u\|_{L^2(\Omega_{2R_0})}). \end{aligned} \quad (75)$$

Here, for each fixed $\delta \in [0, 1)$, the constant C is independent of $\gamma \in [-\delta, 1]$, α , and F . Moreover, the constant β in (74) is given by

$$\begin{aligned} \beta &= \int_{\partial\Omega} y^\perp \cdot (T(u, p)\nu) d\sigma_y + b_\Omega[f], \\ b_\Omega[f] &= \tilde{c}_\Omega[F] + \int_\Omega (y^\perp \cdot f + F_{12} - F_{21})\varphi + \nabla\varphi \cdot (Fy^\perp) dy, \end{aligned} \quad (76)$$

where $b_\Omega[f]$ coincides with $c_\Omega[f]$ when $F \in L_{2,0}^\infty(\Omega)^{2 \times 2}$.

Proof: We may assume that $\int_{\Omega_{2R_0}} p dx = 0$. Let $\varphi \in C_0^\infty(\mathbb{R}^2)$ be a cut-off function satisfying $\varphi(x) = 1$ for $|x| \leq R_0$ and $\varphi(x) = 0$ for $|x| \geq 2R_0$. We introduce the Bogovskii operator \mathbb{B} in the closed annulus $A = \{x \in \mathbb{R}^2 \mid R_0 \leq |x| \leq 2R_0\}$, and set

$$v = (1 - \varphi)u + \mathbb{B}[\nabla\varphi \cdot u], \quad q = (1 - \varphi)p.$$

Note that $\mathbb{B}[\nabla\varphi \cdot u]$ satisfies

$$\text{supp } \mathbb{B}[\nabla\varphi \cdot u] \subset A, \quad \text{div } \mathbb{B}[\nabla\varphi \cdot u] = \nabla\varphi \cdot u, \quad (77)$$

and

$$\|\mathbb{B}[\nabla\varphi \cdot u]\|_{W^{m+1,2}(\Omega)} \leq C\|\nabla\varphi \cdot u\|_{W^{m,2}(\Omega)}, \quad m = 0, 1. \quad (78)$$

See, e.g. Borchers and Sohr [2]. Then $(v, \nabla q)$ satisfies

$$-\Delta v - \alpha(x^\perp \cdot \nabla v - v^\perp) + \nabla q = \text{div } \mathcal{F} + g, \quad \text{div } v = 0, \quad x \in \mathbb{R}^2, \quad (79)$$

where

$$\begin{aligned} \mathcal{F} &= (1 - \varphi)F - \nabla \mathbb{B}[\nabla\varphi \cdot u], \\ g &= F \cdot \nabla\varphi + 2\nabla\varphi \cdot \nabla u + (\Delta\varphi + \alpha x^\perp \cdot \nabla\varphi)u \\ &\quad - \alpha(x^\perp \nabla \mathbb{B}[\nabla\varphi \cdot u] - \mathbb{B}[\nabla\varphi \cdot u]^\perp) - (\nabla\varphi)p. \end{aligned}$$

Note that $\text{supp } g \subset A$ due to (77). Recalling the uniqueness result in Remark 3.2, we find

$$\begin{aligned} u(x) &= v(x) = u_\infty + L[\text{div } \mathcal{F}] + L[g] \\ &= u_\infty + (\tilde{c}[\mathcal{F}] + c[g]) \frac{x^\perp}{4\pi|x|^2} + \mathcal{R}(x), \quad |x| \geq 4R_0, \end{aligned} \quad (80)$$

where $u_\infty \in \mathbb{R}^2$ is a constant vector. Recalling that $R_0 \geq 1$, we see from Theorem 3.1 that $\mathcal{R}(x)$ satisfies

$$\begin{aligned} \|\mathcal{R}\|_{L_{1+\gamma}^\infty(\{|x| \geq 4R_0\})} &\leq C \left(\sup_{|x| \geq 4R_0} |x|^{1+\gamma} |\mathcal{R}[\text{div } \mathcal{F}](x)| + \sup_{|x| \geq 4R_0} |x|^{1+\gamma} |\mathcal{R}[g](x)| \right) \\ &\leq C \left(\|F\|_{L_{2+\gamma}^\infty(\{|x| \geq 2R_0\})} + \sup_{|x| \geq 4R_0} |x|^{-1+\gamma} \|yF\|_{L^1(\{2R_0 \leq |y| \leq \frac{|x|}{2}\})} \right. \\ &\quad + \sup_{|x| \geq 4R_0} \min \left\{ \frac{1}{|\alpha||x|^{2-\gamma}}, |x|^\gamma \right\} \|F\|_{L^1(\{2R_0 \leq |y| \leq \frac{|x|}{2}\})} \\ &\quad + \sup_{|x| \geq 4R_0} |x|^\gamma \left| \lim_{\epsilon \rightarrow 0} \int_{2|y| \geq |x|} e^{-\epsilon|y|^2} (F_{21} - F_{12}) dy \right| \\ &\quad + \left(\sup_{|x| \geq 4R_0} \min \left\{ \frac{1}{|\alpha||x|^{2-\gamma}}, |x|^\gamma \right\} + 1 \right) \|\mathcal{F}\|_{L^1(\{|y| \leq 2R_0\})} \right) \\ &\quad + C(|\alpha|^{-\frac{1+\gamma}{2}} + |\alpha|^{-\frac{1}{2}} + 1) \|g\|_{L^1(\{|x| \leq 2R_0\})}. \end{aligned}$$

Here C depends only on R_0 . It is easy to see

$$\|\mathcal{F}\|_{L^1(\{|x| \leq 2R_0\})} \leq C(\|F\|_{L^2(\Omega_{2R_0})} + \|\nabla u\|_{L^2(\Omega_{2R_0})})$$

by applying (78) and the Poincaré inequality. Similarly, the function g is estimated as

$$\|g\|_{L^1(\{|x| \leq 2R_0\})} \leq C(\|F\|_{L^2(\Omega_{2R_0})} + (1 + |\alpha|)\|\nabla u\|_{L^2(\Omega_{2R_0})} + \|p\|_{L^2(\Omega_{2R_0})}).$$

In order to estimate the pressure term let us recall the condition $\int_{\Omega_{2R_0}} p dx = 0$, which yields from (S_α) ,

$$\begin{aligned} \|p\|_{L^2(\Omega_{2R_0})} &\leq C\|\nabla p\|_{H^{-1}(\Omega_{2R_0})} = C\|\text{div } [F + \nabla u + \alpha(u \otimes x^\perp - x^\perp \otimes u)]\|_{H^{-1}(\Omega_{2R_0})} \\ &\leq C(\|F\|_{L^2(\Omega_{2R_0})} + (1 + |\alpha|)\|\nabla u\|_{L^2(\Omega_{2R_0})}), \end{aligned}$$

where $H^{-1}(\Omega_{2R_0})$ is the topological dual of $W_0^{1,2}(\Omega_{2R_0})$. Collecting these estimates, we obtain (75).

Finally let us determine the coefficient β in (74). In view of (80) it suffices to compute $\tilde{c}[F] + c[g]$. Fix $N \geq 2R_0$ and let $\phi_N \in C_0^\infty(\mathbb{R}^2)$ be a cut-off function such that $\phi_N(x) = 1$ for $|x| \leq N$ and $\phi_N(x) = 0$ for $|x| \geq 2N$. Then we have

$$\begin{aligned} \tilde{c}[F] + c[g] &= \lim_{\epsilon \rightarrow 0} \int_{\mathbb{R}^2} e^{-\epsilon|y|^2} (F_{21} - F_{12})(1 - \phi_N) dy \\ &\quad + \int_{\mathbb{R}^2} (\mathcal{F}_{21} - \mathcal{F}_{12})\phi_N dy + \int_{\mathbb{R}^2} y^\perp \cdot g\phi_N dy \\ &= \tilde{c}_\Omega[F] - \int_{\Omega} (F_{21} - F_{12})\phi_N dy + \int_{\mathbb{R}^2} (\mathcal{F}_{21} - \mathcal{F}_{12})\phi_N dy + \int_{\mathbb{R}^2} y^\perp \cdot g\phi_N dy. \end{aligned} \quad (81)$$

We set $S(v, q) = T(v, q) + \alpha(v \otimes x^\perp + x^\perp \otimes v)$. Since $\operatorname{div} \mathcal{F} + g = -\operatorname{div} S(v, q)$ in \mathbb{R}^2 , the integration by parts and $\nabla y^\perp \cdot S(v, q) = 0$ in \mathbb{R}^2 yield

$$\begin{aligned} &\int_{\mathbb{R}^2} y^\perp \cdot g\phi_N dy \\ &= - \int_{\mathbb{R}^2} \phi_N y^\perp \cdot \operatorname{div} S(v, q) dy - \int_{\mathbb{R}^2} \phi_N y^\perp \cdot \operatorname{div} \mathcal{F} dy \\ &= \int_{\mathbb{R}^2} y^\perp \cdot S(v, q) \nabla \phi_N dy - \int_{\mathbb{R}^2} (\mathcal{F}_{21} - \mathcal{F}_{12})\phi_N dy + \int_{\mathbb{R}^2} \nabla \phi_N \cdot (\mathcal{F} y^\perp) dy. \end{aligned} \quad (82)$$

Since $S(v, q) = S(u, p)$ for $|x| \geq 2R_0$ and $-\operatorname{div} S(u, p) = f$ in Ω , again from the integration parts we have

$$\begin{aligned} \int_{\mathbb{R}^2} y^\perp \cdot S(v, q) \nabla \phi_N dy &= \int_{\Omega} y^\perp \cdot S(u, p) \nabla \phi_N dy \\ &= \int_{\partial\Omega} y^\perp \cdot T(u, p) \nu d\sigma_y + \int_{\Omega} \phi_N y^\perp \cdot f dy. \end{aligned} \quad (83)$$

Here we have used the boundary condition $u = 0$ on $\partial\Omega$. By using the cut-off function φ above, we then compute the second term in the above as

$$\begin{aligned} \int_{\Omega} \phi_N y^\perp \cdot f dy &= \int_{\Omega} \varphi y^\perp \cdot f dy - \int_{\Omega} \nabla(y^\perp \phi_N (1 - \varphi)) F dy \\ &= \int_{\Omega} \varphi y^\perp \cdot f dy + \int_{\Omega} (F_{21} - F_{12})\phi_N (1 - \varphi) dy - \int_{\Omega} \nabla(\phi_N (1 - \varphi)) \cdot (F y^\perp) dy \\ &= \int_{\Omega} \varphi y^\perp \cdot f dy + \int_{\Omega} (F_{21} - F_{12})\phi_N dy - \int_{\Omega} (F_{21} - F_{12})\varphi dy \\ &\quad - \int_{\Omega} \nabla \phi_N \cdot (F y^\perp) dy + \int_{\Omega} \nabla \varphi \cdot (F y^\perp) dy. \end{aligned} \quad (84)$$

Collecting (81) - (84) and using $\mathcal{F} = F$ for $|x| \geq 2R_0$, we obtain

$$\begin{aligned} \tilde{c}[F] + c[g] &= \int_{\partial\Omega} y^\perp \cdot T(u, p) \nu d\sigma_y \\ &\quad + \tilde{c}_\Omega[F] + \int_{\Omega} (y^\perp \cdot f + F_{12} - F_{21})\varphi + \nabla \varphi \cdot (F y^\perp) dy, \end{aligned} \quad (85)$$

as desired. When $F \in L_{2,0}^\infty(\Omega)^{2 \times 2}$ the coefficient $b_\Omega[f]$ coincides with $c_\Omega[f]$ in virtue of (72). The proof is complete. \square

Let us recall that $R_0 \geq 1$ is taken so that $\mathbb{R}^2 \setminus \Omega \subset B_{R_0}(0)$. Let $\varphi \in C_0^\infty(\Omega)$ be a radial cut-off function such that $\varphi(x) = 1$ for $|x| \leq R_0$ and $\varphi(x) = 0$ for $|x| \geq 2R_0$. Then we set

$$V(x) = (1 - \varphi(x)) \frac{x^\perp}{4\pi|x|^2}. \quad (86)$$

Note that V is a radial circular flow satisfying $\operatorname{div} V = 0$ which describes the asymptotic behavior of solutions to the Stokes system $(S_{\alpha, \mathbb{R}^2})$ as is shown in Theorem 3.1. The main result of this section is stated as follows.

Theorem 3.8 *Let $\alpha \in \mathbb{R} \setminus \{0\}$ and $\gamma \in (-1, 1]$. Suppose that $f \in L^2(\Omega)^2$ is of the form $f = \operatorname{div} F$ with $F \in L_{2+\gamma}^\infty(\Omega)^{2 \times 2}$. Assume in addition that $\tilde{c}_\Omega[F]$ converges when $\gamma \in (-1, 0]$. Then there exists a unique solution $(u, \nabla p) \in W_{loc}^{2,2}(\overline{\Omega})^2 \times L_{loc}^2(\overline{\Omega})$ to (S_α) satisfying $\lim_{|x| \rightarrow \infty} |u(x)| = 0$ and*

$$\|\nabla u\|_{L^2(\Omega)} \leq \|F\|_{L^2(\Omega)}, \quad (87)$$

$$\|p\|_{L^2(\Omega_{6R_0})} \leq C(1 + |\alpha|)\|F\|_{L^2(\Omega)}, \quad (88)$$

$$\|\nabla^2 u\|_{L^2(\Omega_{kR_0})} + \|\nabla p\|_{L^2(\Omega_{kR_0})} \leq C(1 + |\alpha|)(\|F\|_{L^2(\Omega)} + \|f\|_{L^2(\Omega_{(k+1)R_0})}), \quad 2 \leq k \leq 5. \quad (89)$$

Moreover, the velocity u is written as

$$u(x) = \beta V(x) + \mathcal{R}_\Omega[f](x), \quad x \in \Omega, \quad (90)$$

where $\beta \in \mathbb{R}$ is given by

$$\begin{aligned} \beta &= \int_{\partial\Omega} y^\perp \cdot (T(u, p)\nu) \, d\sigma_y + b_\Omega[f], \\ b_\Omega[f] &= \tilde{c}_\Omega[F] + \int_{\Omega} (y^\perp \cdot f + F_{12} - F_{21})\varphi + \nabla\varphi \cdot (Fy^\perp) \, dy, \end{aligned} \quad (91)$$

while $\mathcal{R}_\Omega[f]$ satisfies

$$\begin{aligned} \sup_{|x| \geq 4R_0} |x|^{1+\gamma} |\mathcal{R}_\Omega[f](x)| &\leq C \left(\sup_{|x| \geq 2R_0} |x|^{2+\gamma} |F(x)| + \sup_{|x| \geq 4R_0} |x|^{-1+\gamma} \|yF\|_{L_y^1(\Omega_{|x|/2})} \right. \\ &\quad + \sup_{|x| \geq 4R_0} \min \left\{ \frac{1}{|\alpha||x|^{2-\gamma}}, |x|^\gamma \right\} \|F\|_{L_y^1(\Omega_{|x|/2})} \\ &\quad \left. + \sup_{|x| \geq 4R_0} |x|^\gamma \left| \lim_{\epsilon \rightarrow 0} \int_{2|y| \geq |x|} e^{-\epsilon|y|^2} (F_{21} - F_{12}) \, dy \right| \right) \\ &\quad + C(|\alpha|^{-\frac{1+\gamma}{2}} + |\alpha|^{-\frac{1}{2}} + 1)(1 + |\alpha|)\|F\|_{L^2(\Omega)}. \end{aligned} \quad (92)$$

Here, for each fixed $\delta \in [0, 1)$, the constant C is independent of $\gamma \in [-\delta, 1]$, α , and F . If $F \in L_{2,0}^\infty(\Omega)^{2 \times 2}$ then the coefficient $b_\Omega[f]$ coincides with $c_\Omega[f]$.

Proof: We follow the argument of [19, Theorem 2.2]. Since the argument is quite parallel to it, we only give the outline here. (Uniqueness) Let $(u, \nabla p), (u', \nabla p') \in W_{loc}^{2,2}(\overline{\Omega})^2 \times L_{loc}^2(\overline{\Omega})^2$ be solutions to (S_α) with the same f such that $\|\nabla u\|_{L^2(\Omega)}$ and $\|\nabla u'\|_{L^2(\Omega)}$ are finite and $|u(x)| + |u'(x)| \rightarrow \infty$ as $|x| \rightarrow \infty$. Then the difference $(v, \nabla q) = (u - u', \nabla(p - p')) \in W_{loc}^{2,2}(\overline{\Omega})^2 \times L_{loc}^2(\overline{\Omega})^2$ solves (S_α) with $f = 0$ and satisfies $\|\nabla v\|_{L^2(\Omega)} < \infty$ as well as $|v(x)| \rightarrow 0$ as $|x| \rightarrow \infty$. Moreover, the standard elliptic regularity of the Stokes operator implies that $(v, \nabla q)$ is smooth in Ω . Then we can apply [19, Theorem 2.1, (2.8)], which gives $\int_\Omega |Dv|^2 dx = 0$. Hence v is the rigid motion, but the condition $v = 0$ on the boundary leads to $v = 0$ in Ω . Then we obtain $\nabla q = 0$ from the equation. The proof of the uniqueness is complete.

(Existence) Firstly we consider the regularized system

$$\begin{cases} \epsilon u_\epsilon - \Delta u_\epsilon + \alpha(x^\perp \cdot \nabla u_\epsilon - u_\epsilon^\perp) + \nabla p_\epsilon = f, & \operatorname{div} u_\epsilon = 0, & x \in \Omega, \\ u_\epsilon = 0, & & x \in \partial\Omega. \end{cases} \quad (S_\alpha^\epsilon)$$

Here ϵ is a small positive number. For (S_α^ϵ) one can show the existence of the solution $(u_\epsilon, \nabla p_\epsilon)$ satisfying $\int_{\Omega_{2R_0}} p_\epsilon dx = 0$ and the energy estimate

$$\epsilon \|u_\epsilon\|_{L^2(\Omega)}^2 + \frac{1}{2} \|\nabla u_\epsilon\|_{L^2(\Omega)}^2 \leq \frac{1}{2} \|F\|_{L^2(\Omega)}^2. \quad (93)$$

Moreover, the assumption $f \in L^2(\Omega)^2$ and the elliptic regularity for the Stokes operator imply the regularity $u_\epsilon \in W_{loc}^{2,2}(\overline{\Omega})^2$, $\nabla p_\epsilon \in L_{loc}^2(\overline{\Omega})^2$, where in virtue of (93) each seminorm can be bounded uniformly in $\epsilon \in (0, 1)$. Let us recall that $R_0 \geq 1$ is taken so that $\mathbb{R}^2 \setminus \Omega \subset B_{R_0}(0)$ and let $\varphi \in C_0^\infty(\mathbb{R}^2)$ be a radial cut-off function such that $\varphi(x) = 1$ for $|x| \leq R_0$ and $\varphi(x) = 0$ for $|x| \geq 2R_0$. As in the proof of Lemma 3.7, we introduce the Bogovskii operator \mathbb{B} in the closed annulus $A = \{x \in \mathbb{R}^2 \mid R_0 \leq |x| \leq 2R_0\}$, and set

$$v_\epsilon = (1 - \varphi)u_\epsilon + \mathbb{B}[\nabla\varphi \cdot u_\epsilon], \quad q_\epsilon = (1 - \varphi)p_\epsilon.$$

Recall that $\mathbb{B}[\nabla\varphi \cdot u_\epsilon]$ satisfies

$$\operatorname{supp} \mathbb{B}[\nabla\varphi \cdot u_\epsilon] \subset A, \quad \operatorname{div} \mathbb{B}[\nabla\varphi \cdot u_\epsilon] = \nabla\varphi \cdot u_\epsilon, \quad (94)$$

$$\|\mathbb{B}[\nabla\varphi \cdot u_\epsilon]\|_{W^{m+1,2}(\Omega)} \leq C \|\nabla\varphi \cdot u_\epsilon\|_{W^{m,2}(\Omega)}, \quad m = 0, 1. \quad (95)$$

Then $(v_\epsilon, \nabla q_\epsilon)$ satisfies

$$\epsilon v_\epsilon - \Delta v_\epsilon - \alpha(x^\perp \cdot \nabla v_\epsilon - v_\epsilon^\perp) + \nabla q_\epsilon = \operatorname{div} F_\epsilon + g_\epsilon, \quad \operatorname{div} u_\epsilon = 0, \quad x \in \mathbb{R}^2, \quad (96)$$

where

$$\begin{aligned} F_\epsilon &= (1 - \varphi)F - \nabla \mathbb{B}[\nabla\varphi \cdot u_\epsilon], \\ g_\epsilon &= F \cdot \nabla\varphi + \epsilon \mathbb{B}[\nabla\varphi \cdot u_\epsilon] + 2\nabla\varphi \cdot \nabla u_\epsilon + (\Delta\varphi + \alpha x^\perp \cdot \nabla\varphi)u_\epsilon \\ &\quad - \alpha(x^\perp \nabla \mathbb{B}[\nabla\varphi \cdot u_\epsilon] - \mathbb{B}[\nabla\varphi \cdot u_\epsilon]^\perp) - (\nabla\varphi)p_\epsilon. \end{aligned}$$

Note that $\operatorname{supp} g_\epsilon \subset A$ due to (94). Let $\Gamma_\alpha^\epsilon(x, y)$ be the function defined as (61). Then, as is shown in [19] (see also Remark 3.2), the velocity v_ϵ is written as

$$\begin{aligned} v_\epsilon(x) &= \int_{\mathbb{R}^2} \Gamma_\alpha^\epsilon(x, y) \operatorname{div} F_\epsilon(y) dy + \int_{\mathbb{R}^2} \Gamma_\alpha^\epsilon(x, y) g_\epsilon(y) dy \\ &=: w_\epsilon(x) + r_\epsilon(x). \end{aligned} \quad (97)$$

Since $g_\epsilon = 0$ for $|x| \geq 2R_0$ we have from [19, Proposition 3.3],

$$\begin{aligned} \sup_{|x| \geq 4R_0} |x| |r_\epsilon(x)| &\leq C_\alpha \int_{\Omega} (1 + |x|) |g_\epsilon(x)| \, dx \\ &\leq C_\alpha \|g_\epsilon\|_{L^2(\Omega)} \\ &\leq C_\alpha (\|F\|_{L^2(\Omega_{2R_0})} + (1 + |\alpha|) \|\nabla u_\epsilon\|_{L^2(\Omega_{2R_0})} + \|p_\epsilon\|_{L^2(\Omega_{2R_0})}). \end{aligned} \quad (98)$$

Since $\int_{\Omega_{2R_0}} p_\epsilon \, dx = 0$ we have from (S_α^ϵ) ,

$$\|p_\epsilon\|_{L^2(\Omega_{2R_0})} \leq C \|\nabla p_\epsilon\|_{H^{-1}(\Omega_{2R_0})} \leq C (\|F\|_{L^2(\Omega_{2R_0})} + (1 + |\alpha|) \|\nabla u_\epsilon\|_{L^2(\Omega_{2R_0})})$$

Combining this estimate with (93) and (98), we obtain

$$\sup_{|x| \geq 4R_0} |x| |r_\epsilon(x)| \leq C_\alpha \|F\|_{L^2(\Omega)}. \quad (99)$$

Here C_α depends only on α and R_0 , but is independent of $\epsilon \in (0, 1)$. As for w_ϵ , we have from Lemma 3.5, there is $\theta > 0$ such that

$$\begin{aligned} \sup_{|x| \geq 4R_0} |x|^\theta |w_\epsilon(x)| &\leq C (\|F\|_{L_{2+\gamma}^\infty(\{|y| \geq 2R_0\})} + \|F_\epsilon\|_{L_y^1(\{|y| \leq 2R_0\})}) \\ &\leq C (\|F\|_{L_{2+\gamma}^\infty(\{|y| \geq 2R_0\})} + \|F\|_{L^2(\Omega)}). \end{aligned} \quad (100)$$

Collecting (93), (99), (100), and $u_\epsilon \in W_{loc}^{2,2}(\overline{\Omega})^2$ with its uniform bound on $\epsilon \in (0, 1)$, we have

$$\|u_\epsilon\|_{L_\theta^\infty(\Omega)} \leq C_\alpha (\|F\|_{L_{2+\gamma}^\infty(\Omega)} + \|F\|_{L^2(\Omega)}), \quad (101)$$

which is an uniform estimate in $\epsilon \in (0, 1)$. Thus, there are a subsequence, denoted again by $(u_\epsilon, \nabla p_\epsilon)$, and $(u, \nabla p) \in W_{loc}^{2,2}(\overline{\Omega})^2 \times L_{loc}^2(\overline{\Omega})^2$, such that $u_\epsilon \rightharpoonup^* u$ in $L_\theta^\infty(\Omega)^2$, $\nabla u_\epsilon \rightharpoonup \nabla u$ in $L^2(\Omega)^{2 \times 2}$, and $p_\epsilon \rightharpoonup p$ in $W_{loc}^{1,2}(\overline{\Omega})$. It is easy to see that $(u, \nabla p)$ satisfies (S_α) in the sense of distributions (note that each term of (S_α) makes sense at least as a function in $L_{loc}^2(\overline{\Omega})$). The proof of the existence is complete.

(Estimates) We note that the solution $(u, \nabla p)$ obtained in the existence proof above satisfies $\|\nabla u\|_{L^2(\Omega)} \leq \|F\|_{L^2(\Omega)}$ in virtue of (93). Thus (87) holds. Since the pressure p is uniquely determined up to a constant, we may assume $\int_{\Omega_{6R_0}} p \, dx = 0$. Then we have from (S_α) ,

$$\begin{aligned} \|p\|_{L^2(\Omega_{6R_0})} &\leq C \|\nabla p\|_{H^{-1}(\Omega_{6R_0})} \leq C (\|F\|_{L^2(\Omega_{6R_0})} + (1 + |\alpha|) \|\nabla u\|_{L^2(\Omega_{6R_0})}) \\ &\leq C (1 + |\alpha|) \|F\|_{L^2(\Omega)}. \end{aligned}$$

Here C depends only on R_0 . This proves (88). The local estimates (89) follow from the standard cut-off argument and the elliptic estimates for the Stokes system in bounded domains, together with the estimates (87) and (88). Since the argument is rather standard, we omit the details here. The expansion (90) with (91) and the estimate (92) follow from Lemma 3.7 and (87). The proof of Theorem 3.8 is complete. \square

Remark 3.9 Let $R_0 \geq 1$ as in Theorem 3.8 and let $\gamma \in [0, 1)$. Then we have for $|x| \geq 4R_0$,

$$\begin{aligned} \|yF\|_{L_y^1(\Omega_{|x|/2})} &\leq \frac{C}{1-\gamma} |x|^{1-\gamma} \|F\|_{L_{2+\gamma}^\infty(\Omega)}, \\ \|F\|_{L_y^1(\Omega_{|x|/2})} &\leq C \|F\|_{L_{2+\gamma}^\infty(\Omega)} \log |x|. \end{aligned}$$

Here C is independent of γ and F . Since

$$\min \left\{ \frac{1}{|\alpha||x|^{2-\gamma}}, |x|^\gamma \right\} \log |x| \leq |\alpha|^{-\frac{\gamma}{2}} |\log |\alpha||, \quad |\alpha| > 0,$$

we have for $\gamma \in [0, 1]$ and $|\alpha| > 0$, by using (92),

$$\begin{aligned} \sup_{|x| \geq 4R_0} |x|^{1+\gamma} |\mathcal{R}_\Omega[f](x)| &\leq \frac{C}{1-\gamma} \left(|\alpha|^{-\frac{\gamma}{2}} |\log |\alpha|| \|F\|_{L_{2+\gamma}^\infty(\Omega)} + |\alpha|^{-\frac{1+\gamma}{2}} \|F\|_{L^2(\Omega)} \right. \\ &\quad \left. + \sup_{|x| \geq 4R_0} |x|^\gamma \lim_{\epsilon \rightarrow 0} \int_{2|y| \geq |x|} e^{-\epsilon|y|^2} (F_{21} - F_{12}) dy \right). \end{aligned} \quad (102)$$

Here C is independent of $|\alpha| > 0$, $\gamma \in [0, 1]$, and F . The estimate (102) plays a central role to solve the Navier-Stokes equations for small $|\alpha|$ in the next section. We note that $\tilde{c}_\Omega[F]$ and the last term in the right-hand side of (102) do not converge in general when $F \in L_2^\infty(\Omega)^{2 \times 2}$. In solving the Navier-Stokes equations, especially for the case $\gamma = 0$, it is crucial that we only need the decay of the component $F_{21} - F_{12}$, which always vanishes when F is symmetric.

4 Solvability of nonlinear problem

Based on the linear analysis in the previous sections the following Navier-Stokes equations are studied in this section:

$$\begin{cases} -\Delta u - \alpha(x^\perp \cdot \nabla u - u^\perp) + \nabla p = -u \cdot \nabla u + f, & \operatorname{div} u = 0, & x \in \Omega, \\ u = \alpha x^\perp, & & x \in \partial\Omega. \end{cases} \quad (\text{NS}_\alpha)$$

Our aim is to prove, under some conditions on f , the unique existence of solutions $(u, \nabla p)$ to (NS_α) satisfying the asymptotic behavior

$$u(x) = \beta V(x) + o(|x|^{-1}) \quad \text{as } |x| \rightarrow \infty$$

for some $\beta \in \mathbb{R}$, where V is a radial circular flow defined by (86) and coincides with $\frac{x^\perp}{4\pi|x|^2}$ for $|x| \gg 1$. As in the previous sections we fix $R_0 \geq 1$ large enough so that $\mathbb{R}^2 \setminus \Omega \subset B_{R_0}(0)$, and let $\varphi \in C_0^\infty(\mathbb{R}^2)$ be a radial cut-off function satisfying $\varphi(x) = 1$ for $|x| \leq R_0$, $\varphi(x) = 0$ for $|x| \geq 2R_0$. Set

$$U(x) = \varphi(x)x^\perp, \quad (103)$$

which is a radial circular flow supported in the ball $B_{2R_0}(0)$. We also introduce the function space $X_\gamma, \gamma \geq 0$, as follows.

$$X_\gamma = \mathbb{R} \times (\dot{W}_{0,\sigma}^{1,2}(\Omega) \cap L_{1+\gamma}^\infty(\Omega)^2), \quad (104)$$

which is complete under the norm for $(\beta, w) \in X_\gamma$:

$$\|(\beta, w)\|_{X_\gamma} = |\beta| + \|\nabla w\|_{L^2(\Omega)} + \|w\|_{L_{1+\gamma}^\infty(\Omega)}. \quad (105)$$

Let us recall that for $f \in L^2(\Omega)^2$ of the form $f = \operatorname{div} F$ with some $F \in L^2(\Omega)^{2 \times 2}$ the coefficients $c_\Omega[f]$, $\tilde{c}_\Omega[F]$, and $b_\Omega[f]$ are defined as (70) and (91), respectively. The main results of this section are Theorems 4.1, 4.3 below. Let us start from the next theorem.

Theorem 4.1 Let $\gamma \in [0, 1)$. There exists a positive constant $\epsilon = \epsilon(\Omega, \gamma)$ such that the following statement holds. Suppose that $f \in L^2(\Omega)^2$ is of the form $f = \operatorname{div} F$ with some $F \in L_{2+\gamma}^\infty(\Omega)^{2 \times 2}$, and in addition that $F_{21} - F_{12} \in L^1(\Omega)$ when $\gamma = 0$. If $\alpha \neq 0$ and

$$\begin{aligned} & |\alpha|^{\frac{1-\gamma}{2}} |\log |\alpha|| + |\alpha|^{-\frac{\gamma}{2}} |\log |\alpha|| \left(|\alpha|^{-\frac{1}{2}} (|b_\Omega[f]| + \|F\|_{L^2(\Omega)} + \|f\|_{L^2(\Omega_{6R_0})}) \right. \\ & \left. + \|F_{21} - F_{12}\|_{L^1(\Omega)} + |\log |\alpha|| \|F\|_{L_2^\infty(\Omega)} \right) < \epsilon, \end{aligned} \quad (106)$$

then there exists a unique solution $(u, \nabla p) \in W_{loc}^{2,2}(\overline{\Omega})^2 \times L_{loc}^2(\overline{\Omega})^2$ to (NS_α) satisfying

$$\|\nabla u\|_{L^2(\Omega)} \leq \frac{\|F\|_{L^2(\Omega)} + C_2|\alpha|}{\sqrt{1 - C_1|\alpha|}}, \quad (107)$$

and enjoying the expression $u = \alpha U + \beta V + w$ with V defined by (86),

$$\beta = \int_{\partial\Omega} y^\perp \cdot (T(u, p)\nu) d\sigma_y + b_\Omega[f], \quad (108)$$

while

$$\begin{aligned} \|w\|_{L_1^\infty(\Omega)} &\leq C_3 \left(|\alpha|^{-\frac{1}{2}} (|\alpha| + |b_\Omega[f]| + \|F\|_{L^2(\Omega)} + \|f\|_{L^2(\Omega_{6R_0})}) \right. \\ & \left. + |\log |\alpha|| \|F\|_{L_2^\infty(\Omega)} + \|F_{21} - F_{12}\|_{L^1(\Omega)} \right), \end{aligned} \quad (109)$$

and for $\gamma \in (0, 1)$,

$$\begin{aligned} \|w\|_{L_{1+\gamma}^\infty(\Omega)} &\leq C_3 \left(|\alpha|^{-\frac{1+\gamma}{2}} (|\alpha| |\log |\alpha|| + |b_\Omega[f]| + \|F\|_{L^2(\Omega)} + \|f\|_{L^2(\Omega_{6R_0})}) \right. \\ & \left. + (|\alpha|^{-\frac{\gamma}{2}} |\log |\alpha|| + \frac{1}{\gamma}) \|F\|_{L_{2+\gamma}^\infty(\Omega)} \right). \end{aligned} \quad (110)$$

Here ϵ , C_1 , C_2 , and C_3 depend only on Ω and γ , and are taken uniformly with respect to γ in each compact subset of $[0, 1)$.

Remark 4.2 (i) Under the assumption of Theorem 4.1 the coefficient $\tilde{c}_\Omega[F]$ defined in (70) converges absolutely. If $F \in L_{2,0}^\infty(\Omega)^{2 \times 2}$ then $b_\Omega[f]$ in (108) coincides with $c_\Omega[f]$.

(ii) A careful analysis implies that β in Theorem 4.1 is estimated as

$$|\beta| \leq C_4 (|\alpha| + |b_\Omega[f]| + \|F\|_{L^2(\Omega)} + \|f\|_{L^2(\Omega_{6R_0})}), \quad (111)$$

where C_4 depends only on Ω . But we do not go into details in this paper.

(iii) In Theorem 4.1 when $\gamma = 0$ the term w decays with the order $O(|x|^{-1})$ and there is no reason why βV provides a leading term of the asymptotic behavior of u at $|x| \rightarrow \infty$. To achieve this asymptotics we need the additional decay of F such as $F \in L_{2,0}^\infty(\Omega)^{2 \times 2}$; see Theorem 4.3 below.

Proof of Theorem 4.1: In the following argument we will freely use the condition $0 < |\alpha| < e^{-1}$. We look for the solution to (NS_α) of the form

$$u = \alpha U + v, \quad v = \beta V + w, \quad (\beta, w) \in X_\gamma. \quad (112)$$

We need to determine β and w . Inserting (112) into (NS_α) , we see that v is the solution to the system

$$\begin{cases} -\Delta v - \alpha(x^\perp \cdot \nabla v - v^\perp) + \nabla q = \operatorname{div} G_\alpha(\beta, w) + \operatorname{div} H_\alpha(F), & x \in \Omega, \\ \operatorname{div} v = 0, & x \in \Omega, \\ v = 0, & x \in \partial\Omega. \end{cases} \quad (\text{NS}'_\alpha)$$

Here

$$\begin{aligned} q &= p + P, \\ G_\alpha(\beta, w) &= -\alpha(U \otimes w + w \otimes U) - \beta(V \otimes w + w \otimes V) - w \otimes w, \\ H_\alpha(F) &= \alpha \nabla U + F. \end{aligned}$$

and we may assume that $\int_{\Omega_{6R_0}} q \, dx = 0$. Note that we have used the relations $x^\perp \cdot \nabla U - U^\perp = 0$ and the radial scalar function $P = P(|x|)$ is taken so that $\nabla P = \operatorname{div}[(\alpha U + \beta V) \otimes (\alpha U + \beta V)]$. Both of these follow from the direct calculation. The proof of the unique existence below relies on the standard Banach fixed point argument in a suitable class of functions. To this end we firstly introduce the closed convex set $\mathcal{B}_{\vec{\delta}, \gamma}$ in X_0 :

$$\begin{aligned} \mathcal{B}_{\vec{\delta}, \gamma} = \mathcal{B}_{(\delta_1, \delta_2, \delta_3), \gamma} &= \{(\beta, w) \in X_0 \mid |\beta| + \|\nabla w\|_{L^2(\Omega)} + \|w\|_{L^\infty(\Omega_{5R_0})} \leq \delta_1, \\ &\quad \|w\|_{L_1^\infty(\Omega)} \leq \delta_2, \quad \|w\|_{L_{1+\gamma}^\infty(\Omega)} \leq \delta_3\}. \end{aligned} \quad (113)$$

Here we have set $\vec{\delta} = (\delta_1, \delta_2, \delta_3)$, and the positive numbers $\delta_1, \delta_2, \delta_3$ with $\delta_2 \leq \delta_3$ will be suitably determined later. We note that the following inclusion always holds.

$$\mathcal{B}_{(\delta_1, \delta_2, \delta_3), \gamma} \subset \mathcal{B}_{(\delta_1, \delta_2, \delta_2), 0}. \quad (114)$$

For any $\omega = (\beta, w) \in \mathcal{B}_{\vec{\delta}, \gamma}$, let $(u_\omega, \nabla q_\omega)$ be the unique solution in Theorem 3.8 to the linear system

$$\begin{cases} -\Delta u_\omega - \alpha(x^\perp \cdot \nabla u_\omega - u_\omega^\perp) + \nabla q_\omega = \operatorname{div} G_\alpha(\beta, w) + \operatorname{div} H_\alpha(F), & x \in \Omega, \\ \operatorname{div} u_\omega = 0, & x \in \Omega, \\ u_\omega = 0, & x \in \partial\Omega. \end{cases}$$

Our aim is to show the unique existence of $(\beta, w) \in \mathcal{B}_{\vec{\delta}, \gamma}$ such that $u_\omega = u_{(\beta, w)} = \beta V + w$ for suitably chosen and sufficiently small $0 < \delta_1 \leq \delta_2 < e^{-2}$ and $\delta_3 \geq \delta_2$. We remark that the smallness is not required for δ_3 when γ is positive. Let us start from the estimates for $G_\alpha(\beta, w)$. Firstly we estimate its L^2 norm as

$$\begin{aligned} &\|G_\alpha(\beta, w)\|_{L^2(\Omega)} \\ &\leq C \left(|\alpha| \|\nabla w\|_{L^2(\Omega)} + |\beta| \|w\|_{L_1^\infty(\Omega)} + \|w\|_{L_1^\infty(\Omega)} \|\nabla w\|_{L^2(\Omega)} |\log \|\nabla w\|_{L^2(\Omega)}| \right). \end{aligned} \quad (115)$$

Here for the nonlinear term we have used (162) and the smallness of δ_1 and δ_2 to obtain

$$\begin{aligned} \|w \otimes w\|_{L^2(\Omega)} &\leq C \|w\|_{L_1^\infty(\Omega)} \|(1 + |x|)^{-1} w\|_{L^2(\Omega)} \\ &\leq C \|w\|_{L_1^\infty(\Omega)} \|\nabla w\|_{L^2(\Omega)} |\log \|\nabla w\|_{L^2(\Omega)}|. \end{aligned}$$

On the other hand, it is not difficult to see that

$$\|G_\alpha(\beta, w)\|_{L_{2+\gamma'}^\infty(\Omega)} \leq C(|\alpha| + |\beta| + \|w\|_{L_1^\infty(\Omega)})\|w\|_{L_{1+\gamma'}^\infty(\Omega)}, \quad 0 \leq \gamma' \leq \gamma, \quad (116)$$

$$\|\operatorname{div} G_\alpha(\beta, w)\|_{L^2(\Omega_{6R_0})} \leq C(|\alpha| + |\beta| + \|w\|_{L^\infty(\Omega_{6R_0})})\|\nabla w\|_{L^2(\Omega)} \quad (117)$$

and

$$\|H_\alpha(F)\|_{L^2(\Omega)} \leq C(|\alpha| + \|F\|_{L^2(\Omega)}), \quad (118)$$

$$\|H_\alpha(F)\|_{L_{2+\gamma'}^\infty(\Omega)} \leq C(|\alpha| + \|F\|_{L_{2+\gamma'}^\infty(\Omega)}), \quad 0 \leq \gamma' \leq \gamma, \quad (119)$$

$$\|\operatorname{div} H_\alpha(F)\|_{L^2(\Omega_{6R_0})} \leq C(|\alpha| + \|f\|_{L^2(\Omega_{6R_0})}). \quad (120)$$

Then we can apply the result of Theorem 3.8. To simplify the notation we set

$$\begin{aligned} M(\alpha, \beta, F, w) &= (|\alpha| + |\beta|)\|\nabla w\|_{L^2(\Omega)} + |\beta|\|w\|_{L_1^\infty(\Omega)} \\ &\quad + \|w\|_{L_1^\infty(\Omega)}\|\nabla w\|_{L^2(\Omega)}\log\|\nabla w\|_{L^2(\Omega)} + |\alpha| + \|F\|_{L^2(\Omega)}. \end{aligned} \quad (121)$$

From (87), (115), and (118), we have

$$\|\nabla u_{(\beta, w)}\|_{L^2(\Omega)} \leq CM(\alpha, \beta, F, w). \quad (122)$$

Moreover, by the Sobolev embedding $W^{2,2}(\Omega_{5R_0}) \hookrightarrow L^\infty(\Omega_{5R_0})$ and (87) - (89) combined with (115), (117), (118), (120), and $\|w\|_{L^\infty(\Omega_{6R_0})} \leq \|w\|_{L_1^\infty(\Omega)}$, we have

$$\begin{aligned} &\|u_{(\beta, w)}\|_{L^\infty(\Omega_{5R_0})} + \|u_{(\beta, w)}\|_{W^{2,2}(\Omega_{5R_0})} + \|q_{(\beta, w)}\|_{W^{1,2}(\Omega_{5R_0})} \\ &\leq C(M(\alpha, \beta, F, w) + \|f\|_{L^2(\Omega_{6R_0})}). \end{aligned} \quad (123)$$

Set $\tilde{F} = G_\alpha(\beta, w) + H_\alpha(F)$ and $\tilde{f} = \operatorname{div} \tilde{F}$. By Theorem 3.8, the velocity $u_\omega = u_{(\beta, w)}$ is written as

$$u_\omega = \psi[\omega]V + R[\omega],$$

where $R[\omega]$ belongs to $L_{1+\gamma}^\infty(\Omega)^2$ and $\psi[\omega]$ is given by

$$\begin{aligned} \psi[\omega] &= \int_{\partial\Omega} y^\perp \cdot T(u_\omega, q_\omega) \nu \, d\sigma_y + b_\Omega[\tilde{f}], \\ b_\Omega[\tilde{f}] &= \tilde{c}_\Omega[\tilde{F}] + \int_{\Omega} (y^\perp \cdot \tilde{f} + \tilde{F}_{12} - \tilde{F}_{21})\varphi + \nabla\varphi \cdot (\tilde{F}y^\perp) \, dy. \end{aligned} \quad (124)$$

We observe that $\tilde{c}_\Omega[G_\alpha(\beta, w)] = 0$ and

$$\int_{\Omega} (x^\perp \cdot \operatorname{div} G_\alpha(\beta, w) + G_\alpha(\beta, w)_{12} - G_\alpha(\beta, w)_{21})\varphi + \nabla\varphi \cdot (G_\alpha(\beta, w)x^\perp) \, dx = 0.$$

Here we have used the facts that $G_\alpha(\beta, w)$ is symmetric and its trace on the boundary is zero. This implies $b_\Omega[\operatorname{div} G_\alpha(\beta, w)] = 0$. Moreover, we have

$$b_\Omega[\Delta U] = c_\Omega[\Delta U] = 0$$

in virtue of the computation

$$\begin{aligned}
\int_{\Omega} x^{\perp} \cdot \Delta U \, dx &= \int_{\Omega} x \cdot \nabla \operatorname{rot} U \, dx = \int_{\partial\Omega} x \cdot n (\operatorname{rot} U) \, d\sigma_x - 2 \int_{\Omega} \operatorname{rot} U \, dx \\
&= \int_{\partial\Omega} x \cdot n (\operatorname{rot} U) \, d\sigma_x - 2 \int_{\partial\Omega} n^{\perp} \cdot U \, d\sigma_x \\
&= 2 \int_{\partial\Omega} x \cdot n \, d\sigma_x - 2 \int_{\partial\Omega} n^{\perp} \cdot x^{\perp} \, d\sigma_x = 0.
\end{aligned}$$

Here $\operatorname{rot} U = \partial_1 U_2 - \partial_2 U_1$ and we have used the identity $U(x) = x^{\perp}$ near $\partial\Omega$. Hence, (124) is in fact written as

$$\psi[\omega] = \int_{\partial\Omega} y^{\perp} \cdot T(u_{\omega}, q_{\omega}) \nu \, d\sigma_y + b_{\Omega}[f]. \quad (125)$$

Here we note that $b_{\Omega}[f] = c_{\Omega}[f]$ when $F \in L^1(\Omega)^{2 \times 2}$ due to (72).

Now let us define the mapping $\Phi : \mathcal{B}_{\vec{\delta}, \gamma} \rightarrow X_0$ as

$$\Phi[\omega] = (\psi[\omega], R[\omega]), \quad \psi[\omega] \text{ is given by (125)}, \quad R[\omega] = u_{\omega} - \psi[\omega]V. \quad (126)$$

Recalling the inclusion (114), our aim is to show

- (i) Φ is a mapping from $\mathcal{B}_{\vec{\delta}, \gamma}$ into $\mathcal{B}_{\vec{\delta}, \gamma}$, and
- (ii) Φ is a contraction on $\mathcal{B}_{(\delta_1, \delta_2, \delta_2), 0}$ in the topology of X_0 . i.e., there is $\tau \in (0, 1)$ such that $\|\Phi(\omega_1) - \Phi(\omega_2)\|_{X_0} \leq \tau \|\omega_1 - \omega_2\|_{X_0}$ for any $\omega_1, \omega_2 \in \mathcal{B}_{(\delta_1, \delta_2, \delta_2), 0}$.

To prove (i) let us estimate $\psi[\omega]$ based on the representation (125). By the trace theorem we have

$$\left| \int_{\partial\Omega} y^{\perp} \cdot T(u_{\omega}, q_{\omega}) \nu \, d\sigma_y \right| \leq C(\|\nabla u_{\omega}\|_{W^{1,2}(\Omega_{5R_0})} + \|q_{\omega}\|_{W^{1,2}(\Omega_{5R_0})}),$$

Hence we have from (123),

$$|\psi[\omega]| \leq C(M(\alpha, \beta, F, w) + |b_{\Omega}[f]| + \|f\|_{L^2(\Omega_{6R_0})}). \quad (127)$$

Next let us estimate $R[\omega]$. Firstly we observe from (123), (122), and (127) that

$$\begin{aligned}
\|R[\omega]\|_{L^{\infty}(\Omega_{5R_0})} + \|\nabla R[\omega]\|_{L^2(\Omega)} &= \|u_{\omega} - \psi[\omega]V\|_{L^{\infty}(\Omega_{5R_0})} + \|\nabla(u_{\omega} - \psi[\omega]V)\|_{L^2(\Omega)} \\
&\leq C(\|u_{\omega}\|_{L^{\infty}(\Omega_{5R_0})} + \|\nabla u_{\omega}\|_{L^2(\Omega)} + |\psi[\omega]|) \\
&\leq C(M(\alpha, \beta, F, w) + |b_{\Omega}[f]| + \|f\|_{L^2(\Omega_{6R_0})}).
\end{aligned} \quad (128)$$

On the other hand, we have from (102) and by the condition $F_{21} - F_{12} \in L^1(\Omega)$, for any $\gamma' \in [0, \gamma]$,

$$\begin{aligned}
\|R[\omega]\|_{L^{\infty}_{1+\gamma'}(\{|x| \geq 4R_0\})} &\leq \frac{C}{1-\gamma'} \left(|\alpha|^{-\frac{1+\gamma'}{2}} \|G_{\alpha}(\beta, w) + H_{\alpha}(F)\|_{L^2(\Omega)} \right. \\
&\quad \left. + |\alpha|^{-\frac{\gamma'}{2}} |\log |\alpha|| \|G_{\alpha}(\beta, w) + H_{\alpha}(F)\|_{L^{\infty}_{2+\gamma'}(\Omega)} + d_{\gamma'}[F] \right), \\
d_{\gamma'}[F] &= \sup_{|x| \geq 4R_0} |x|^{\gamma'} \left| \int_{2|y| \geq |x|} (F_{21} - F_{12}) \, dy \right|,
\end{aligned} \quad (129)$$

where C is independent of γ' , γ , and α . Here we have used that $G_\alpha(\beta, w)$ is symmetric and that $U = 0$ for $|x| \geq 2R_0$ by its definition. Note that $d_0[F] \leq \|F_{21} - F_{12}\|_{L^1(\Omega)}$ holds, which will be used later. Combining (128) with (129), (115), (116), (118), and (119), we obtain for $\gamma' \in [0, \gamma]$,

$$\begin{aligned} \|R[\omega]\|_{L_{1+\gamma'}^\infty(\Omega)} &\leq \frac{C}{1-\gamma'} \left\{ |b_\Omega[f]| + \|f\|_{L^2(\Omega_{6R_0})} + |\alpha|^{-\frac{1+\gamma'}{2}} M(\alpha, \beta, F, w) + d_{\gamma'}[F] \right. \\ &\quad + |\alpha|^{-\frac{\gamma'}{2}} |\log |\alpha|| (|\alpha| + |\beta| + \|w\|_{L_1^\infty(\Omega)}) \|w\|_{L_{1+\gamma'}^\infty(\Omega)} \\ &\quad \left. + |\alpha|^{-\frac{\gamma'}{2}} |\log |\alpha|| (|\alpha| + \|F\|_{L_{2+\gamma'}^\infty(\Omega)}) \right\}. \end{aligned} \quad (130)$$

Now we observe that for sufficiently small δ_1 and δ_2 (depending only on Ω so far) the function $M(\alpha, \beta, F, w)$ is bounded from above as

$$M(\alpha, \beta, F, w) \leq (|\alpha| + \delta_1 + \delta_2 |\log \delta_1|) \delta_1 + |\alpha| + \|F\|_{L^2(\Omega)}. \quad (131)$$

Here we have used the fact that $\rho(r) = r |\log r|$ is monotone increasing on $(0, e^{-1}]$, which implies $\|\nabla w\|_{L^2(\Omega)} |\log \|\nabla w\|_{L^2(\Omega)}| \leq \delta_1 |\log \delta_1|$. By taking (127), (128), and (131) into account, we assume that $|\alpha|$, $\|F\|_{L^2(\Omega)}$, $|b_\Omega[f]|$, and $\|f\|_{L^2(\Omega_{6R_0})}$ are small enough so that

$$\delta_1 = 16(C_0 + 1)(|\alpha| + \|F\|_{L^2(\Omega)} + |b_\Omega[f]| + \|f\|_{L^2(\Omega_{6R_0})}) < \frac{1}{16(C_0 + 1)}. \quad (132)$$

Here C_0 is the largest constant of C appearing in (127), (128), and (130) (larger than 1 without loss of generality), and then, C_0 is independent of γ and α . Then for $\delta_2 \in (0, \frac{1}{16(C_0+1)|\log \delta_1|}]$ we see from (131),

$$M(\alpha, \beta, F, w) \leq \frac{1}{4(C_0 + 1)} \delta_1. \quad (133)$$

Thus, (127) and (128) imply that for $\delta_2 \in (0, \frac{1}{16(C_0+1)|\log \delta_1|}]$,

$$|\psi[\omega]| + \|\nabla R[\omega]\|_{L^2(\Omega)} + \|R[\omega]\|_{L^\infty(\Omega_{5R_0})} \leq \frac{\delta_1}{2} \quad \text{for all } \omega \in \mathcal{B}_{\vec{\delta}, \gamma}.$$

Next we focus on $\|R[\omega]\|_{L_1^\infty(\Omega)}$. Taking (130) with $\gamma' = 0$ and (132) (with $|\alpha| < e^{-1}$) into account, we set δ_2 as

$$\delta_2 = \frac{16(C_0 + 1)}{|\log \delta_1|} \left(|\alpha|^{-\frac{1}{2}} \delta_1 + |\log |\alpha|| (|\alpha| + \|F\|_{L_2^\infty(\Omega)}) + \|F_{21} - F_{12}\|_{L^1(\Omega)} \right), \quad (134)$$

which is smaller than $\frac{1}{16(C_0+1)|\log \delta_1|}$ if $|\alpha|$ and the data related to F appearing in (132) and (134) are small enough, while δ_2 is larger than δ_1 since $\delta_1 \geq |\alpha|$ and $|\alpha|^{\frac{1}{2}} |\log |\alpha|| \leq 1$ for $|\alpha| < e^{-1}$. Note that $d_0[F] \leq \|F_{21} - F_{12}\|_{L^1(\Omega)}$ is also taken into account in the choice of (134). The key observation here is that, when $f = F = 0$, the numbers δ_1 and δ_2 are of the order $O(|\alpha|)$ and $O(|\alpha|^{\frac{1}{2}})$ for $|\alpha| \ll 1$, respectively. Then the term

$C|\log |\alpha||(|\alpha| + |\beta| + \|w\|_{L_1^\infty(\Omega)})$ in the right-hand side of (130) with $\gamma' = 0$ is bounded from above by

$$C_0|\log |\alpha||(|\alpha| + \delta_1 + \delta_2) \leq \frac{1}{32}, \quad (135)$$

if $\gamma \in [0, 1)$ and if $|\alpha|$ and the data related to F (and $f = \operatorname{div} F$) appearing in (132) and (134) are sufficiently small. Note that, since δ_2 is at best of the order $O(|\alpha|^{\frac{1}{2}})$, the condition $\gamma \in [0, 1)$ is crucial to ensure (135). Precisely, we need the smallness such as

$$|\alpha|^{\frac{1}{2}}|\log |\alpha|| + \kappa_\alpha(F) < \epsilon(\Omega) \ll 1, \quad (136)$$

where

$$\begin{aligned} \kappa_\alpha(F) := & |\alpha|^{-\frac{1}{2}}|\log |\alpha||(|b_\Omega[f]| + \|F\|_{L^2(\Omega)} + \|f\|_{L^2(\Omega_{6R_0})}) \\ & + |\log |\alpha||\|F_{21} - F_{12}\|_{L^1(\Omega)} + (\log |\alpha|)^2\|F\|_{L^\infty(\Omega)}. \end{aligned} \quad (137)$$

Here the number $\epsilon(\Omega)$ depends only on Ω and is independent of α and γ , and we also note that $\kappa_\alpha[F]$ does not contain the number γ in its definition. Under the above smallness condition we have from (130) with $\gamma' = 0$ and the choice of δ_2 ,

$$\|R[\omega]\|_{L_1^\infty(\Omega)} \leq \frac{\delta_2}{2} \quad \text{for all } \omega \in \mathcal{B}_{\delta, \gamma},$$

as desired. In the above argument the number δ_3 can be arbitrary.

Next we estimate the norm $\|R[\omega]\|_{L_{1+\gamma}^\infty(\Omega)}$ (in the case γ is positive). To bound the term

$$\frac{C}{1-\gamma}|\alpha|^{-\frac{\gamma}{2}}|\log |\alpha||(|\alpha| + |\beta| + \|w\|_{L_1^\infty(\Omega)})$$

in the right-hand side of (130) with $\gamma' = \gamma$, we need the additional smallness for δ_1 and δ_2 depending on γ :

$$\frac{C_0}{1-\gamma}|\alpha|^{-\frac{\gamma}{2}}|\log |\alpha||(|\alpha| + \delta_1 + \delta_2) \leq \frac{1}{32}. \quad (138)$$

Precisely, in the case γ is positive, δ_1 and δ_2 are required to have the smallness as

$$|\alpha|^{\frac{1-\gamma}{2}}|\log |\alpha|| + |\alpha|^{-\frac{\gamma}{2}}\kappa_\alpha(F) < \epsilon_\gamma(\Omega) \ll 1, \quad (139)$$

where the number $\epsilon_\gamma(\Omega)$ depends on Ω on γ , contrary to the case of $\epsilon(\Omega)$ in (136). We note that $\epsilon_0(\Omega) = \epsilon(\Omega)$ and $\epsilon_\gamma(\Omega)$ is taken so that it is monotone decreasing and continuous on $\gamma \in [0, 1)$ in virtue of (130). Then we set δ_3 as

$$\delta_3 = 2\left(|\alpha|^{-\frac{1+\gamma}{2}}\delta_1 + |\alpha|^{-\frac{\gamma}{2}}|\log |\alpha||\|F\|_{L_{2+\gamma}^\infty(\Omega)} + d_\gamma[F]\right), \quad (140)$$

Then we can conclude from (130) with $\gamma' = \gamma$ and (135) that

$$\|R[\omega]\|_{L_{1+\gamma}^\infty(\Omega)} \leq \frac{\delta_3}{2} \quad \text{for all } \omega \in \mathcal{B}_{\delta, \gamma}.$$

It should be emphasized here that the argument works even if δ_3 itself is large. We have now shown that Φ is a mapping from $\mathcal{B}_{\vec{\delta}, \gamma}$ into $\mathcal{B}_{\vec{\delta}, \gamma}$ with the choice of δ_j in (132), (134), and (140) for $j = 1, 2, 3$, respectively.

Next let us show that Φ is a contraction mapping on $\mathcal{B}_{(\delta_1, \delta_2, \delta_2), 0}$. For convenience we set $\vec{\beta} = (\beta_1, \beta_2)$, and $\mathbf{w} = (w_1, w_2)$ for $\omega_j = (\beta_j, w_j) \in \mathcal{B}_{(\delta_1, \delta_2, \delta_2), 0}$, $j = 1, 2$. We also set

$$h = (\psi[\omega_1] - \psi[\omega_2])V + R[\omega_1] - R[\omega_2], \quad (141)$$

which is equal to $u_{\omega_1} - u_{\omega_2}$, and hence, the velocity h satisfies

$$\begin{cases} -\Delta h - \alpha(x^\perp \cdot \nabla h - h^\perp) + \nabla q = \operatorname{div} G'_\alpha(\vec{\beta}, \mathbf{w}), & \operatorname{div} h = 0, & x \in \Omega, \\ h = 0, & x \in \partial\Omega, \end{cases}$$

where $q = q_{\omega_1} - q_{\omega_2} \in W_{loc}^{1,2}(\overline{\Omega})$. Here $G'_\alpha(\vec{\beta}, \mathbf{w})$ is given by

$$\begin{aligned} G'_\alpha(\vec{\beta}, \mathbf{w}) &= -\alpha(U \otimes (w_1 - w_2) + (w_1 - w_2) \otimes U) - (\beta_1 - \beta_2)(V \otimes w_1 + w_1 \otimes V) \\ &\quad - \beta_2(V \otimes (w_1 - w_2) + (w_1 - w_2) \otimes V) - w_1 \otimes (w_1 - w_2) - (w_1 - w_2) \otimes w_2. \end{aligned}$$

Below we give the estimates of $G'_\alpha(\vec{\beta}, \mathbf{w})$, where the estimate for the L^2 norm of the term $V \otimes w_1 + w_1 \otimes V$ has to be carefully computed: in principle, we need to estimate it by δ_1 rather than δ_2 , for their dependence on $|\alpha|$ is essentially different. Due to the negative power on $|\alpha|$ in the linear estimate (102) this is crucial to show that Φ is a contraction mapping. Because of this reasoning we apply (162) in Lemma A.1 by recalling the bound $|V(x)| \leq C(1 + |x|)^{-1}$, which yields

$$\|V \otimes w_1 + w_1 \otimes V\|_{L^2(\Omega)} \leq C\|\nabla w_1\|_{L^2(\Omega)} |\log \|\nabla w_1\|_{L^2(\Omega)}| \quad (142)$$

Here we have used the smallness of $\|\nabla w_1\|_{L^2(\Omega)} + \|w_1\|_{L_1^\infty(\Omega)}$. Similarly, also for the nonlinear term in $G'_\alpha(\vec{\beta}, \mathbf{w})$ we will apply (162). Then it follows that

$$\begin{aligned} &\|G'_\alpha(\vec{\beta}, \mathbf{w})\|_{L^2(\Omega)} \\ &\leq C(|\alpha| \|\nabla(w_1 - w_2)\|_{L^2(\Omega)} + |\beta_1 - \beta_2| \|\nabla w_1\|_{L^2(\Omega)} |\log \|\nabla w_1\|_{L^2(\Omega)}| \\ &\quad + |\beta_2| \|w_1 - w_2\|_{L_1^\infty(\Omega)} + \|w_1 - w_2\|_{L_1^\infty(\Omega)} \|\nabla \mathbf{w}\|_{L^2(\Omega)} |\log \|\nabla \mathbf{w}\|_{L^2(\Omega)}|) \\ &\leq C(|\alpha| \|\nabla(w_1 - w_2)\|_{L^2(\Omega)} + \delta_1 |\log \delta_1| |\beta_1 - \beta_2| + 3\delta_1 |\log \delta_1| \|w_1 - w_2\|_{L_1^\infty(\Omega)}) \\ &\leq C(|\alpha| + \delta_1 |\log \delta_1|) \|\omega_1 - \omega_2\|_{X_0}, \end{aligned} \quad (143)$$

and on the other hand, it is not difficult to see

$$\begin{aligned} \|G'_\alpha(\vec{\beta}, \mathbf{w})\|_{L_2^\infty(\Omega)} &\leq C(|\alpha| \|w_1 - w_2\|_{L_1^\infty(\Omega)} + |\beta_1 - \beta_2| \|w_1\|_{L_1^\infty(\Omega)} \\ &\quad + |\beta_2| \|w_1 - w_2\|_{L_1^\infty(\Omega)} + \|\mathbf{w}\|_{L_1^\infty(\Omega)} \|w_1 - w_2\|_{L_1^\infty(\Omega)}) \\ &\leq C(\delta_2 |\beta_1 - \beta_2| + (|\alpha| + \delta_1 + 2\delta_2) \|w_1 - w_2\|_{L_1^\infty(\Omega)}) \\ &\leq C(|\alpha| + \delta_1 + \delta_2) \|\omega_1 - \omega_2\|_{X_0}. \end{aligned} \quad (144)$$

Similarly, we observe that

$$\begin{aligned}
& \|\operatorname{div} G'_\alpha(\vec{\beta}, \mathbf{w})\|_{L^2(\Omega_{5R_0})} \\
& \leq C(|\alpha| \|\nabla(w_1 - w_2)\|_{L^2(\Omega)} + |\beta_1 - \beta_2| \|\nabla w_1\|_{L^2(\Omega_{5R_0})} + |\beta_2| \|\nabla(w_1 - w_2)\|_{L^2(\Omega_{5R_0})} \\
& \quad + \|w_1\|_{L^\infty(\Omega_{5R_0})} \|\nabla(w_1 - w_2)\|_{L^2(\Omega)} + \|\nabla w_2\|_{L^2(\Omega)} \|w_1 - w_2\|_{L^\infty(\Omega)}) \\
& \leq C(|\alpha| \|\nabla(w_1 - w_2)\|_{L^2(\Omega)} + \delta_1 |\beta_1 - \beta_2| + \delta_1 \|\nabla(w_1 - w_2)\|_{L^2(\Omega)} \\
& \quad + \delta_1 \|\nabla(w_1 - w_2)\|_{L^2(\Omega)} + \delta_1 \|w_1 - w_2\|_{L_1^\infty(\Omega)}) \\
& \leq C(|\alpha| + \delta_1) \|\omega_1 - \omega_2\|_{X_0}.
\end{aligned} \tag{145}$$

By applying Theorem 3.8, we have the representation of the velocity h as

$$h = \left(\int_{\partial\Omega} y^\perp \cdot T(h, q) \nu \, d\sigma_y \right) V + \mathcal{R}_\Omega[\operatorname{div} G'_\alpha(\vec{\beta}, \mathbf{w})]. \tag{146}$$

Here we have used $b_\Omega[\operatorname{div} G'_\alpha(\vec{\beta}, \mathbf{w})] = 0$ again, which follows from the symmetry of $G'_\alpha(\vec{\beta}, \mathbf{w})$ and from the fact that the trace of $G'_\alpha(\vec{\beta}, \mathbf{w})$ on $\partial\Omega$ is zero. Since $h = u_{\omega_1} - u_{\omega_2}$ and $q = q_{\omega_1} - q_{\omega_2}$ we see from the definitions of $T(h, q)$ and $\psi[\omega_j]$ in (125),

$$\int_{\partial\Omega} y^\perp \cdot T(h, q) \nu \, d\sigma_y = \psi[\omega_1] - \psi[\omega_2],$$

and thus, we also have from (141) and (146),

$$\mathcal{R}_\Omega[\operatorname{div} G'_\alpha(\vec{\beta}, \mathbf{w})] = R[\omega_1] - R[\omega_2].$$

In virtue of (87) - (89) we see

$$\begin{aligned}
\left| \int_{\partial\Omega} y^\perp \cdot T(h, q) \nu \, d\sigma_y \right| & \leq C(\|\nabla h\|_{W^{1,2}(\Omega_{4R_0})} + \|q\|_{W^{1,2}(\Omega_{4R_0})}) \\
& \leq C(\|G'_\alpha(\vec{\beta}, \mathbf{w})\|_{L^2(\Omega)} + \|\operatorname{div} G'_\alpha(\vec{\beta}, \mathbf{w})\|_{L^2(\Omega_{5R_0})}).
\end{aligned} \tag{147}$$

A similar argument as in the derivation of (128) yields

$$\begin{aligned}
& \|\mathcal{R}_\Omega[\operatorname{div} G'_\alpha(\vec{\beta}, \mathbf{w})]\|_{L^\infty(\Omega_{4R_0})} + \|\nabla \mathcal{R}_\Omega[\operatorname{div} G'_\alpha(\vec{\beta}, \mathbf{w})]\|_{L^2(\Omega)} \\
& \leq C(\|G'_\alpha(\vec{\beta}, \mathbf{w})\|_{L^2(\Omega)} + \|\operatorname{div} G'_\alpha(\vec{\beta}, \mathbf{w})\|_{L^2(\Omega_{5R_0})}).
\end{aligned} \tag{148}$$

Moreover, by applying (102) we see that the term $\mathcal{R}_\Omega[\operatorname{div} G'_\alpha(\vec{\beta}, \mathbf{w})]$ satisfies

$$\begin{aligned}
& \|\mathcal{R}_\Omega[\operatorname{div} G'_\alpha(\vec{\beta}, \mathbf{w})]\|_{L_1^\infty(\{|x| \geq 4R_0\})} \\
& \leq C \left(|\alpha|^{-\frac{1}{2}} \|G'_\alpha(\vec{\beta}, \mathbf{w})\|_{L^2(\Omega)} + |\log |\alpha|| \|G'_\alpha(\vec{\beta}, \mathbf{w})\|_{L_2^\infty(\Omega)} \right).
\end{aligned} \tag{149}$$

Here we have used again the symmetry of $G'_\alpha(\vec{\beta}, \mathbf{w})$. Combining (147), (148), and (149) with (143), (144), and (145), we obtain for sufficiently small $|\alpha| \neq 0$ and $\kappa_\alpha[F]$ in (137),

$$\begin{aligned}
& \|\Phi[\omega_1] - \Phi[\omega_2]\|_{X_0} \\
& = |\psi[\omega_1] - \psi[\omega_2]| + \|\nabla(R[\omega_1] - R[\omega_2])\|_{L^2(\Omega)} + \|R[\omega_1] - R[\omega_2]\|_{L_1^\infty(\Omega)} \\
& \leq C \left(|\alpha|^{-\frac{1}{2}} (|\alpha| + \delta_1 |\log \delta_1|) + |\log |\alpha|| (|\alpha| + \delta_1 + \delta_2) \right) \|\omega_1 - \omega_2\|_{X_0} \\
& \leq \frac{3}{4} \|\omega_1 - \omega_2\|_{X_0},
\end{aligned} \tag{150}$$

that is, the map Φ is a contraction on $\mathcal{B}_{(\delta_1, \delta_2, \delta_2), 0}$. Here we have used the estimates $|\log \delta_1| \leq |\log |\alpha||$ and $\delta_1 \leq 2^{-1} |\alpha|^{\frac{1}{2}} |\log |\alpha||^{-1}$ if $\delta_1 \geq |\alpha|$ and the data related to F appearing (132) are small enough. Therefore, there exists a fixed point $\omega = (\beta, w)$ of Φ in $\mathcal{B}_{\delta, \gamma}$, which is unique in $\mathcal{B}_{(\delta_1, \delta_2, \delta_2), 0}$. By the definition of Φ in (126), we see that the fixed point $\omega = (\beta, w)$ satisfies

$$u_\omega = u_{(\beta, w)} = \psi[\omega]V + R[\omega] = \beta V + w,$$

which is the solution to (NS'_α) , as desired. Let us set $v = \beta V + w$ for the fixed point $(\beta, w) \in \mathcal{B}_{\delta, \gamma}$. The local regularity of $v \in W_{loc}^{2,2}(\overline{\Omega})^2$ as well as $\nabla q \in L_{loc}^2(\overline{\Omega})^2$ follows from the standard elliptic regularity of the Stokes operator by regarding the nonlinear term, which belongs to $L^2(\Omega)^2$ by the above construction, as a given external force. This leads to the regularity $u \in W_{loc}^{2,2}(\overline{\Omega})^2$ and $\nabla p \in L_{loc}^2(\overline{\Omega})^2$ for the solution $(u, \nabla p)$ to (NS_α) by (112). Next we observe that $v = \beta V + w$ solves

$$\begin{cases} -\Delta v - \alpha(x^\perp \cdot \nabla w - w^\perp) + \nabla \tilde{q} = -\operatorname{div}(\alpha U \otimes v + v \otimes \alpha U + v \otimes v) \\ \quad \quad \quad + \operatorname{div} H_\alpha(F), \quad x \in \Omega, \\ \operatorname{div} v = 0, \quad x \in \Omega, \\ v = 0, \quad x \in \partial\Omega. \end{cases} \quad (NS''_\alpha)$$

Here we have used the identity $x^\perp \cdot \nabla V - V^\perp = 0$ by the definition of V . Let us take the approximation of v of the form

$$v^{(N)} = \chi_N \beta V + w^{(N)}, \quad w^{(N)} = \chi_N w - \mathbb{B}_N[\nabla \chi_N \cdot w], \quad N \gg 1, \quad (151)$$

where $\chi_N(|x|)$ is the radial cut-off function satisfying $\chi_N = 1$ for $|x| \leq N$, $\chi_N = 0$ for $|x| \geq 2N$, and $|\nabla \chi_N| \leq CN^{-1}$, while \mathbb{B}_N is the Bogovskii operator in the closed annulus $A_N = \{N \leq |x| \leq 2N\}$ which satisfies

$$\operatorname{supp} \mathbb{B}_N[\nabla \chi_N \cdot w] \subset A_N, \quad \operatorname{div} \mathbb{B}_N[\nabla \chi_N \cdot w] = \nabla \chi_N \cdot w$$

and

$$\begin{aligned} N^{-1} \|\mathbb{B}_N[\nabla \chi_N \cdot w]\|_{L^2(\Omega)} + \|\nabla \mathbb{B}_N[\nabla \chi_N \cdot w]\|_{L^2(\Omega)} &\leq C \|\nabla \mathbb{B}_N[\nabla \chi_N \cdot w]\|_{L^2(\Omega)} \\ &\leq C \|\nabla \chi_N \cdot w\|_{L^2(\Omega)}. \end{aligned} \quad (152)$$

Here C is independent of N ; see, e.g. Borchers and Sohr [2, Theorem 2.10]. Then, by multiplying $v^{(N)}$ both sides of the first equation in (NS''_α) and integrating over Ω , we obtain

$$\begin{aligned} \langle \nabla v, \nabla v^{(N)} \rangle_{L^2(\Omega)} - \alpha \langle w, x^\perp \cdot \nabla w^{(N)} - (w^{(N)})^\perp \rangle_{L^2(\Omega)} \\ = \langle v \otimes v + \alpha U \otimes \bar{v} + v \otimes \alpha U, \nabla v^{(N)} \rangle_{L^2(\Omega)} - \langle H_\alpha(F), \nabla v^{(N)} \rangle_{L^2(\Omega)} \end{aligned} \quad (153)$$

from the integration by parts. Here we have used again the identity for the radial circular flow: $x^\perp \cdot \nabla(\chi_N V) - \chi_N V^\perp = 0$. It is easy to see from (152) and $w \in \dot{W}_{0,\sigma}^{1,2}(\Omega) \cap L_{1+\gamma}^\infty(\Omega)^2$ that

$$\begin{aligned} \langle \nabla v, \nabla v^{(N)} \rangle_{L^2(\Omega)} &\rightarrow \langle \nabla v, \nabla v \rangle_{L^2(\Omega)}, \\ \langle v \otimes v, \nabla v^{(N)} \rangle_{L^2(\Omega)} &\rightarrow \langle v \otimes v, \nabla v \rangle_{L^2(\Omega)} = 0, \\ \langle \alpha U \otimes v + v \otimes \alpha U, \nabla v^{(N)} \rangle_{L^2(\Omega)} &\rightarrow \langle \alpha U \otimes v + v \otimes \alpha U, \nabla v \rangle_{L^2(\Omega)} = \alpha \langle v \otimes U, \nabla v \rangle_{L^2(\Omega)}, \\ \langle H_\alpha(F), \nabla v^{(N)} \rangle_{L^2(\Omega)} &\rightarrow \langle H_\alpha(F), \nabla v \rangle_{L^2(\Omega)}, \end{aligned}$$

as $N \rightarrow \infty$. As for the term $\langle w, (w^{(N)})^\perp \rangle_{L^2(\Omega)}$ we see

$$\begin{aligned}
|\langle w, (w^{(N)})^\perp \rangle_{L^2(\Omega)}| &= |\langle w, \mathbb{B}_N[\nabla \chi_N \cdot w]^\perp \rangle_{L^2(\Omega)}| \\
&\leq \|w\|_{L^2(\{N \leq |x| \leq 2N\})} \|\mathbb{B}_N[\nabla \chi_N \cdot w]\|_{L^2(\Omega)} \\
&\leq CN \|w\|_{L^2(\{N \leq |x| \leq 2N\})} \|\nabla \chi_N \cdot w\|_{L^2(\Omega)} \\
&\leq CN^{-2\gamma} \|w\|_{L_{1+\gamma}^\infty(\Omega)}^2 \\
&\begin{cases} \rightarrow 0 & (N \rightarrow \infty) & \text{if } \gamma > 0, \\ \leq C \|w\|_{L_1^\infty(\Omega)}^2 & & \text{if } \gamma = 0. \end{cases}
\end{aligned}$$

It remains to consider the term $\langle w, x^\perp \cdot \nabla w^{(N)} \rangle_{L^2(\Omega)}$. From the integration by parts and from $x^\perp \cdot \nabla \chi_N = 0$, $\operatorname{div}(x^\perp \chi_N) = 0$, and $\operatorname{supp} \mathbb{B}_N[\nabla \chi_N \cdot w] \subset A_N$ we have

$$\begin{aligned}
|\langle w, x^\perp \cdot \nabla w^{(N)} \rangle_{L^2(\Omega)}| &= |\langle w, x^\perp \cdot \nabla \mathbb{B}_N[\nabla \chi_N \cdot w] \rangle_{L^2(\Omega)}| \\
&\leq N \|w\|_{L^2(\{N \leq |x| \leq 2N\})} \|\nabla \mathbb{B}_N[\nabla \chi_N \cdot w]\|_{L^2(\Omega)} \\
&\leq CN^{-2\gamma} \|w\|_{L_{1+\gamma}^\infty(\Omega)}^2 \\
&\begin{cases} \rightarrow 0 & (N \rightarrow \infty) & \text{if } \gamma > 0, \\ \leq C \|w\|_{L_1^\infty(\Omega)}^2 & & \text{if } \gamma = 0. \end{cases}
\end{aligned}$$

Here we have also used (152). Collecting these above, we have arrived at the identity

$$\langle \nabla v, \nabla v \rangle_{L^2(\Omega)} = \alpha \langle v \otimes U, \nabla v \rangle_{L^2(\Omega)} - \langle H_\alpha(F), \nabla v \rangle_{L^2(\Omega)} \quad \text{when } \gamma > 0. \quad (154)$$

In particular, from the Poincaré inequality $|\langle v \otimes U, \nabla v \rangle_{L^2(\Omega)}| \leq C \|\nabla v\|_{L^2(\Omega)}^2$ we obtain the estimate

$$(1 - C|\alpha|) \|\nabla v\|_{L^2(\Omega)}^2 \leq \|F + \alpha \nabla U\|_{L^2(\Omega)}^2 \quad \text{when } \gamma > 0, \quad (155)$$

which shows (107) for the case $\gamma > 0$ by the relation $u = \alpha U + v$. Note that the constant C in (155) depends only on R_0 and is independent of α and γ . To obtain the energy inequality for the case $\gamma = 0$ we first consider the approximation of F and f such that

$$F_n(x) = e^{-\frac{1}{n}|x|^2} F(x), \quad f_n = \operatorname{div} F_n. \quad (156)$$

Then $F_n \in L_{2+\gamma}^\infty(\Omega)^{2 \times 2}$ for $\gamma > 0$ and

$$\begin{aligned}
\lim_{n \rightarrow \infty} b_\Omega[f_n - f] &= \lim_{n \rightarrow \infty} \|F - F_n\|_{L^2(\Omega)} = \lim_{n \rightarrow \infty} \|f_n - f\|_{L^2(\Omega_{6R_0})} = 0, \\
\lim_{n \rightarrow \infty} \|(F - F_n)_{21} - (F - F_n)_{12}\|_{L^1(\Omega)} &= 0, \quad \|F_n\|_{L_2^\infty(\Omega)} \leq \|F\|_{L_2^\infty(\Omega)}.
\end{aligned} \quad (157)$$

Here we have used the condition $F_{21} - F_{12} \in L^1(\Omega)$ for the convergence of $b_\Omega[f_n]$. Assume that

$$|\alpha|^{\frac{1}{2}} |\log |\alpha|| + \kappa_\alpha[F] < \epsilon(\Omega),$$

and we fix α . Then there is a unique fixed point (β, w) of Φ in $\mathcal{B}_{(\delta_1, \delta_2, \delta_2), 0}$. On the other hand, since α is fixed, there is $\gamma_0 > 0$ such that

$$\sup_{0 \leq \gamma \leq \gamma_0} (|\alpha|^{\frac{1-\gamma}{2}} |\log |\alpha|| + |\alpha|^{-\frac{\gamma}{2}} \kappa_\alpha[F]) < \epsilon_{\gamma_0}(\Omega).$$

Here we have used the fact that $\epsilon_0(\Omega) = \epsilon(\Omega)$ and $\epsilon_\gamma(\Omega)$ is continuous on $\gamma \in [0, 1)$. Hence, in view of (157) and (137), there is $N \gg 1$ such that

$$\sup_{n \geq N} \sup_{0 \leq \gamma \leq \gamma_0} (|\alpha|^{\frac{1-\gamma}{2}} |\log |\alpha|| + |\alpha|^{-\frac{\gamma}{2}} \kappa_\alpha[F_n]) < \epsilon_{\gamma_0}(\Omega).$$

Let $(v_n, \nabla \tilde{q}_n)$ with $v_n = \beta_n V + w_n$, $n \geq N$, be the unique solution to (NS''_α) with F replaced by F_n such that $(\beta_n, w_n) \in \mathcal{B}_{(\delta_1, \delta_2, \delta_3^{(n)})}, \gamma \subset \mathcal{B}_{(\delta_1, \delta_2, \delta_2), 0}$ with some $\gamma \in (0, \gamma_0]$. Note that for sufficiently large n , we can take the same δ_1 and δ_2 . Then (154) implies

$$\|\nabla v_n\|_{L^2(\Omega)}^2 = \alpha \langle v_n \otimes U, \nabla v_n \rangle_{L^2(\Omega)} - \langle H_\alpha(F), \nabla v_n \rangle_{L^2(\Omega)}. \quad (158)$$

Since $(\beta_n, w_n) \in \mathcal{B}_{(\delta_1, \delta_2, \delta_2), 0}$ we have uniform estimates of $(v_n, \nabla \tilde{q}_n)$, and thus, we find a subsequence, denoted again by $(v_n, \nabla \tilde{q}_n)$, such that $\beta_n \rightarrow \beta_\infty$,

$$\begin{aligned} w_n &\rightharpoonup w_\infty \quad \text{in} \quad W_{loc}^{2,2}(\overline{\Omega})^2, & \tilde{q}_n &\rightharpoonup \tilde{q}_\infty \quad \text{in} \quad W_{loc}^{1,2}(\overline{\Omega}), \\ \nabla w_n &\rightharpoonup \nabla w_\infty \quad \text{in} \quad L^2(\Omega)^{2 \times 2}, & w_n &\rightharpoonup^* w_\infty \quad \text{in} \quad L_1^\infty(\Omega)^2, \end{aligned}$$

and $w_n \rightarrow w_\infty$ strongly in $W_{loc}^{1,2}(\overline{\Omega})^2$. Moreover, we observe from (154) that $v_\infty = \beta_\infty V + w_\infty$ satisfies the energy inequality

$$\|\nabla v_\infty\|_{L^2(\Omega)}^2 \leq \alpha \langle v_\infty \otimes U, \nabla v_\infty \rangle_{L^2(\Omega)} - \langle H_\alpha(F), \nabla v_\infty \rangle_{L^2(\Omega)}. \quad (159)$$

It is also easy to see that $(v_\infty, \nabla \tilde{q}_\infty)$ is a solution to (NS''_α) and $(\beta_\infty, w_\infty) \in \mathcal{B}_{(\delta_1, \delta_2, \delta_2), 0}$. By the uniqueness of the fixed point of Φ in $\mathcal{B}_{(\delta_1, \delta_2, \delta_2), 0}$, we have $(\beta_\infty, w_\infty) = (\beta, w)$. Therefore, (159) holds with v_∞ replaced by $v = \beta V + w$, as desired. Thus we have (107) also when $F \in L_2^\infty(\Omega)^{2 \times 2}$ and $F_{21} - F_{12} \in L^1(\Omega)$.

The estimates (109) and (110) follow from the fact $\|w\|_{L_1^\infty(\Omega)} \leq \delta_2$ and $\|w\|_{L_{1+\gamma}^\infty(\Omega)} \leq \delta_3$ together with the definitions of δ_j in (134), (140), and $d_\gamma[F] \leq C\gamma^{-1}\|F\|_{L_{2+\gamma}^\infty(\Omega)}$ when $\gamma > 0$. As for the identity (108) on the coefficient β , we observe from (125),

$$\beta = \int_{\partial\Omega} y^\perp \cdot T(v, q) \nu \, d\sigma_y + b_\Omega[f].$$

Since $v = u - \alpha x^\perp$ and $q = p + P$ near $\partial\Omega$, where $P = P(|x|)$ is a radial function and has been taken so that $\nabla P = \text{div}[(\alpha U + \beta V) \otimes (\alpha U + \beta V)]$, the straightforward calculations yield

$$\int_{\partial\Omega} y^\perp \cdot (T(v, q) \nu) \, d\sigma_y = \int_{\partial\Omega} y^\perp \cdot (T(u, p) \nu) \, d\sigma_y.$$

Thus (108) holds. The proof of Theorem 4.1 is complete. \square

Finally we consider the case $F \in L_{2,0}^\infty(\Omega)^{2 \times 2}$. Combining Theorem 4.1 with Theorem 4.3 below, we obtain Theorem 1.1.

Theorem 4.3 *Assume that $f = \text{div } F$ satisfies the conditions in Theorem 4.1 for $\gamma = 0$. Assume in addition that $F \in L_{2,0}^\infty(\Omega)^{2 \times 2}$. Then the remainder w in Theorem 4.1 belongs to $L_{1,0}^\infty(\Omega)^2$.*

Proof: The proof is very similar to the derivation of the energy inequality for the case $\gamma = 0$ in the proof of Theorem 4.1. We set F_n and f_n as in (156). Then F_n and f_n satisfy (157), and moreover, the additional condition $F \in L_{2,0}^\infty(\Omega)^{2 \times 2}$ implies

$$\|F_n - F\|_{L_2^\infty(\Omega)} \rightarrow 0, \quad n \rightarrow \infty. \quad (160)$$

As in the proof of Theorem 4.1, let $(v_n, \nabla q_n)$, $v_n = \beta_n V + w_n$, $n \gg 1$, be the solution to (NS''_α) with F replaced by F_n such that $(\beta_n, w_n) \in \mathcal{B}_{(\delta_1, \delta_2, \delta_3^{(n)}), \gamma} \subset \mathcal{B}_{(\delta_1, \delta_2, \delta_2), 0}$ with some $\gamma \in (0, 1)$. Since $w_n \in L_{1+\gamma}^\infty(\Omega)^2$ and $\gamma > 0$ it suffices to show that (β_n, w_n) converges to (β, w) in $\mathbb{R} \times L_1^\infty(\Omega)^2$, where $v = \beta V + w$ is the solution to (NS''_α) . To prove this we observe that the difference $h = v - v_n$ solves

$$\begin{cases} -\Delta h - \alpha(x^\perp \cdot \nabla h - h^\perp) + \nabla q = \operatorname{div} G'_\alpha(\vec{\beta}, \mathbf{w}) + \operatorname{div}(F - F_n), & x \in \Omega, \\ \operatorname{div} h = 0, & x \in \Omega, \\ h = 0, & x \in \partial\Omega. \end{cases}$$

Here we have set $\vec{\beta} = (\beta, \beta_n)$, $\mathbf{w} = (w, w_n)$, and

$$\begin{aligned} G'_\alpha(\vec{\beta}, \mathbf{w}) = & -\alpha(U \otimes (w - w_n) + (w - w_n) \otimes U) - (\beta - \beta_n)(V \otimes w + w \otimes V) \\ & - \beta_n(V \otimes (w - w_n) + (w - w_n) \otimes V) - w \otimes (w - w_n) - (w - w_n) \otimes w_n. \end{aligned}$$

Then the same argument as in the derivation of (150) shows

$$\begin{aligned} \|(\beta, w) - (\beta_n, w_n)\|_{X_0} &\leq \frac{3}{4} \|(\beta, w) - (\beta_n, w_n)\|_{X_0} \\ &+ C \left(|b_\Omega[f - f_n]| + \|F - F_n\|_{L^2(\Omega)} + \|f - f_n\|_{L^2(\Omega_{6R_0})} \right. \\ &\left. + \|(F - F_n)_{21} - (F - F_n)_{12}\|_{L^1(\Omega)} + \|F - F_n\|_{L_2^\infty(\Omega)} \right), \end{aligned}$$

where C is independent of n . Thus, (β_n, w_n) converges to (β, w) in $\mathbb{R} \times L_1^\infty(\Omega)^2$, which shows $w \in L_{1,0}^\infty(\Omega)^2$. The proof is complete. \square

Appendix

We will prove the Hardy type inequality in two-dimensional exterior domains, which is used in the proof of Theorem 4.1.

Lemma A.1 *Let Ω be an exterior domain in \mathbb{R}^2 . Then it follows that*

$$\left\| \frac{f}{1 + |x|} \right\|_{L^2(\Omega)} \leq C \|\nabla f\|_{L^2(\Omega)} \log \left(e + \frac{\|f\|_{L_1^\infty(\Omega)}}{\|\nabla f\|_{L^2(\Omega)}} \right) \quad (161)$$

for any $f \in \dot{W}_0^{1,2}(\Omega) \cap L_1^\infty(\Omega)$. Here C depends only on Ω . In particular, if

$$e \|\nabla f\|_{L^2(\Omega)} + \|f\|_{L_1^\infty(\Omega)} \leq 1,$$

then

$$\left\| \frac{f}{1 + |x|} \right\|_{L^2(\Omega)} \leq C \|\nabla f\|_{L^2(\Omega)} \left| \log \|\nabla f\|_{L^2(\Omega)} \right|. \quad (162)$$

Proof: Take $x_0 \in \mathbb{R}^2 \setminus \overline{\Omega}$ and $0 < r_0 < e^{-1}$ so that $B_{r_0}(x_0) \subset \mathbb{R}^2 \setminus \overline{\Omega}$. By considering the zero extension of f to \mathbb{R}^2 , it suffices to show (161) for $\Omega = \mathbb{R}^2$ and $f \in \dot{W}^{1,2}(\mathbb{R}^2) \cap L_1^\infty(\mathbb{R}^2)$ such that $f = 0$ in $B_{r_0}(x_0)$. Fix $R > 2|x_0|$. By the condition $f(x_0) = 0$ and the mean value theorem in the integral form we have

$$\begin{aligned} \frac{|f(x)|}{1+|x|} &\leq \frac{|x-x_0|}{1+|x|} \int_0^1 |(\nabla f)(\sigma(x-x_0)+x_0)| d\sigma \\ &\leq (1+|x_0|) \int_{\frac{r_0}{|x-x_0|}}^1 |(\nabla f)(\sigma(x-x_0)+x_0)| d\sigma, \quad x \in \mathbb{R}^2 \setminus B_{r_0}(x_0), \end{aligned}$$

which gives

$$\begin{aligned} \left\| \frac{f}{1+|x|} \right\|_{L^2(\{|x-x_0| \leq R\})} &\leq (1+|x_0|) \int_{\frac{r_0}{R}}^1 \sigma^{-1} \|\nabla f\|_{L^2(\mathbb{R}^2)} d\sigma \\ &\leq (1+|x_0|) (|\log R| + |\log r_0|) \|\nabla f\|_{L^2(\mathbb{R}^2)}. \end{aligned} \quad (163)$$

On the other hand, we have

$$\begin{aligned} \left\| \frac{f}{1+|x|} \right\|_{L^2(\{|x-x_0| \geq R\})} &\leq \left\| \frac{1}{(1+|x|)^2} \right\|_{L^2(\{|x| \geq \frac{R}{2}\})} \|f\|_{L_1^\infty(\mathbb{R}^2)} \\ &\leq \frac{C}{R^3} \|f\|_{L_1^\infty(\mathbb{R}^2)}. \end{aligned} \quad (164)$$

If $\|f\|_{L_1^\infty(\mathbb{R}^2)} \leq 2|x_0| \|\nabla f\|_{L^2(\mathbb{R}^2)}$ then we obtain (161) from (163) and (164) with $R = 2|x_0| + 1$. If $\|f\|_{L_1^\infty(\mathbb{R}^2)} \geq 2|x_0| \|\nabla f\|_{L^2(\mathbb{R}^2)}$ then we take $R = e + \frac{\|f\|_{L_1^\infty(\mathbb{R}^2)}}{\|\nabla f\|_{L^2(\mathbb{R}^2)}}$, which yields again from (163) and (164) that

$$\left\| \frac{f}{1+|x|} \right\|_{L^2(\mathbb{R}^2)} \leq C |\log r_0| (1+|x_0|) \|\nabla f\|_{L^2(\mathbb{R}^2)} \log \left(e + \frac{\|f\|_{L_1^\infty(\mathbb{R}^2)}}{\|\nabla f\|_{L^2(\mathbb{R}^2)}} \right). \quad (165)$$

Here we have used $|\log r_0| \geq 1$ and $|\log R| \geq 1$, and C is a numerical constant. Thus (161) holds. The proof is complete. \square
